LECTURE 12

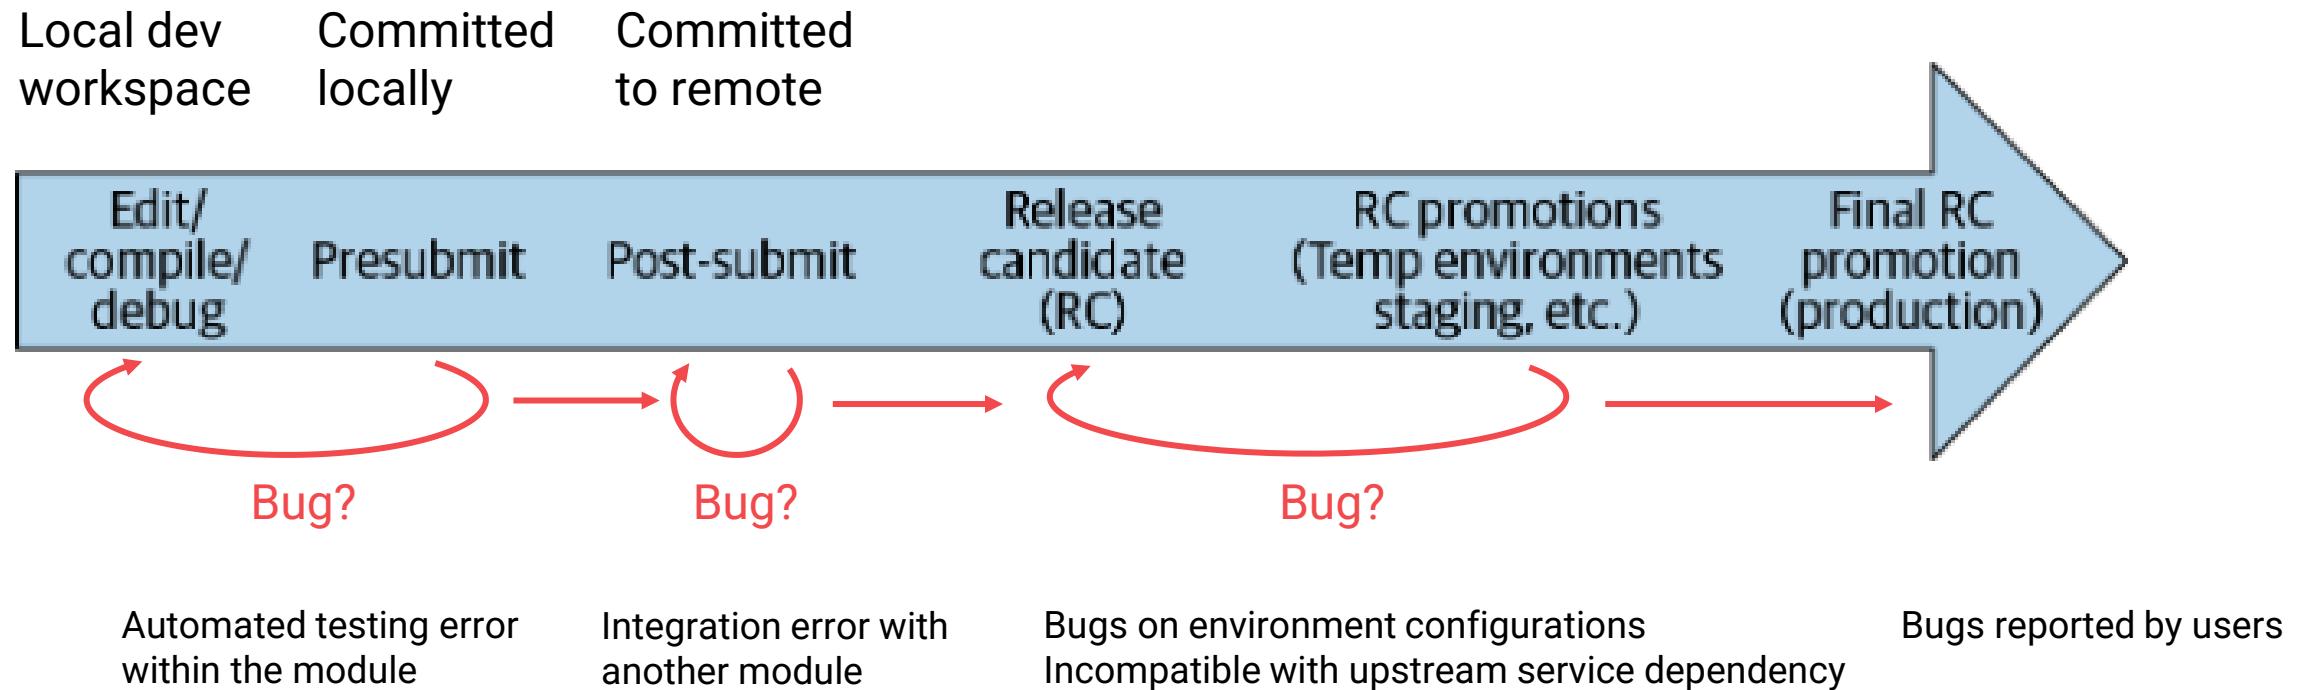

- CI/CD
- Deployment Strategy
- Cloud-native Applications
- Deployment Pipelines

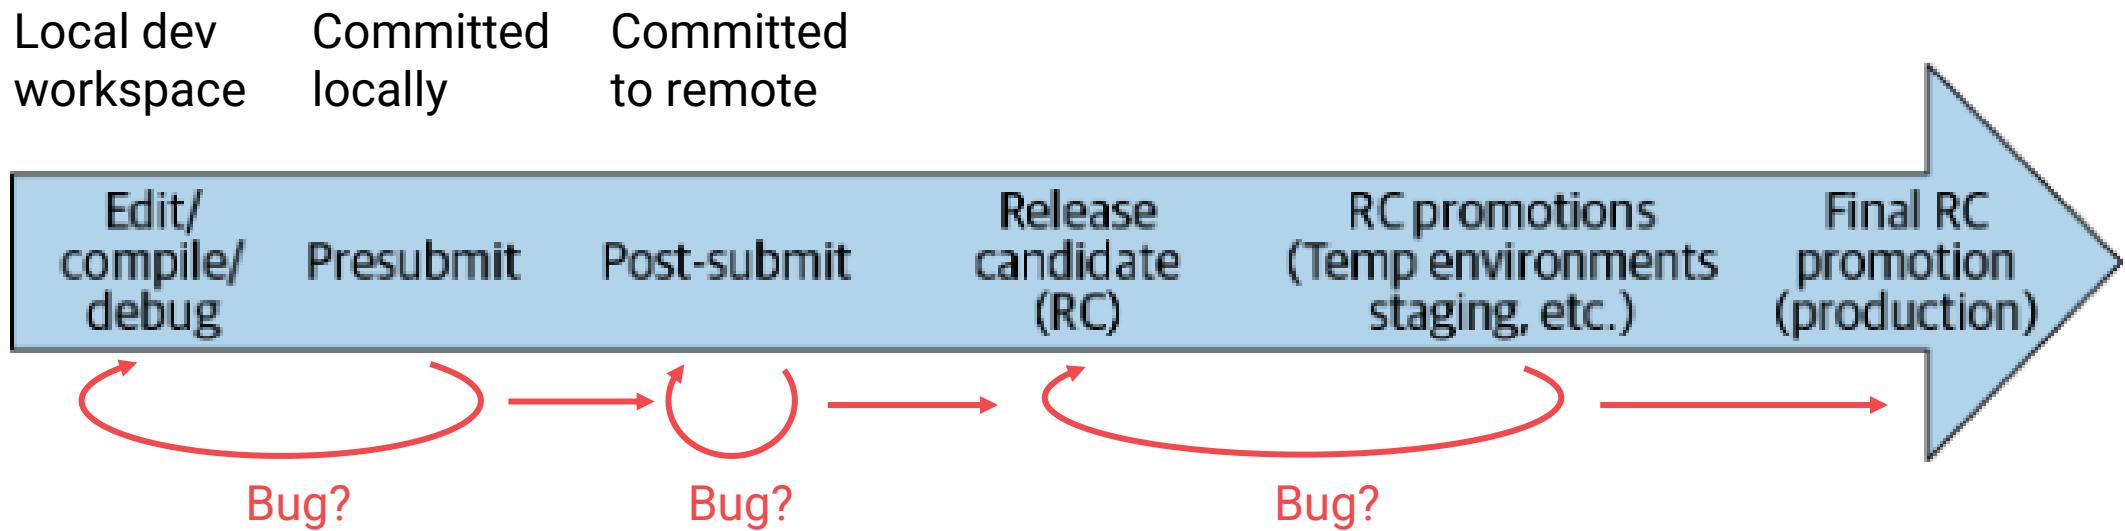

WHERE ARE WE NOW?

LIFE OF A CODE CHANGE

LIFE OF A CODE CHANGE

To minimize the cost of bugs, we need a **feedback loop** whenever we **integrate** a code change

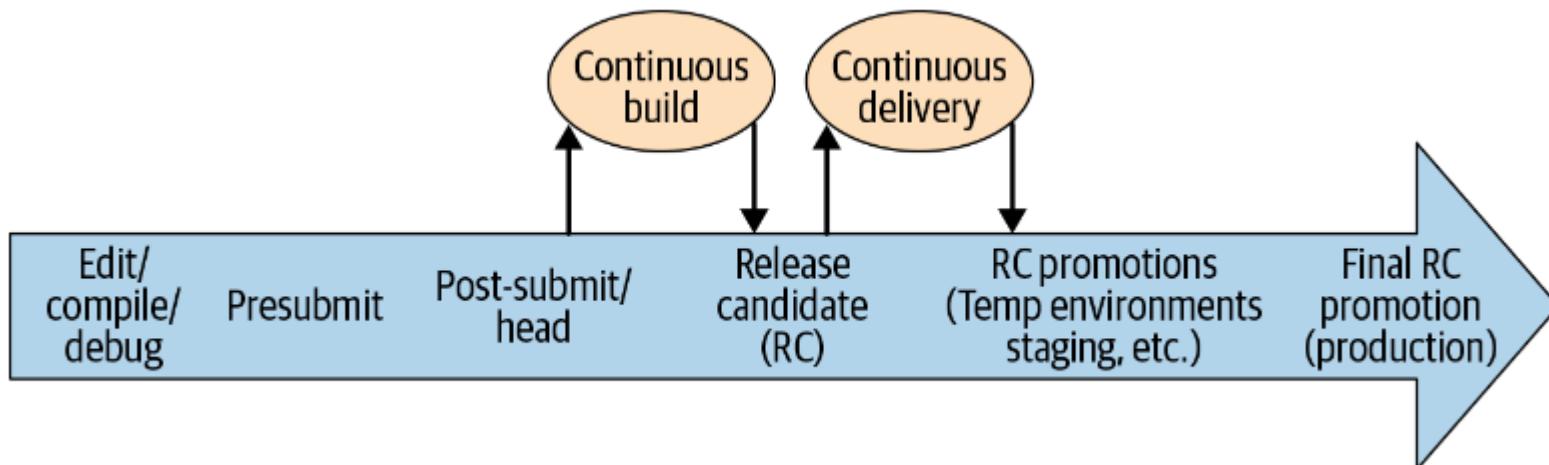

CONTINUOUS INTEGRATION (CI)

- CI is a software development practice where members of a team integrate their work frequently
- Each integration is verified by an automated build (including test) to detect integration errors as quickly as possible

The fundamental goal of CI is to automatically catch problematic changes as early as possible.

CONTINUOUS INTEGRATION (CI)

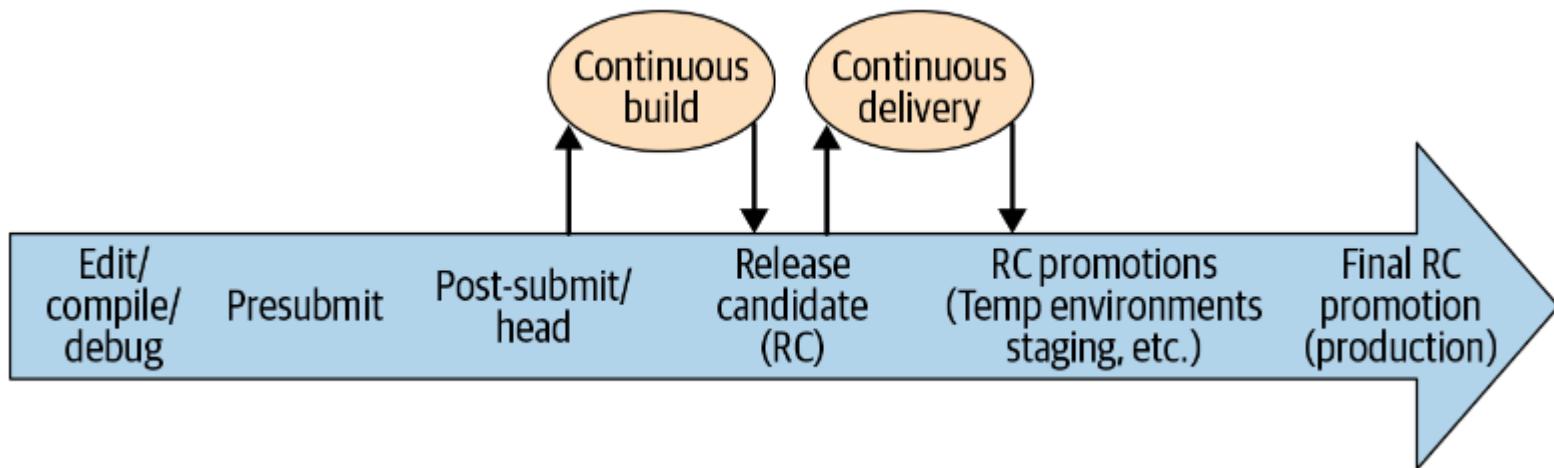

- CI, specifically, automates the build and release processes, with a **Continuous Build** and **Continuous Delivery**.
- **Continuous testing** is applied throughout the entire process (e.g., unit/integration/system test, etc.)

CONTINUOUS BUILD (CB)

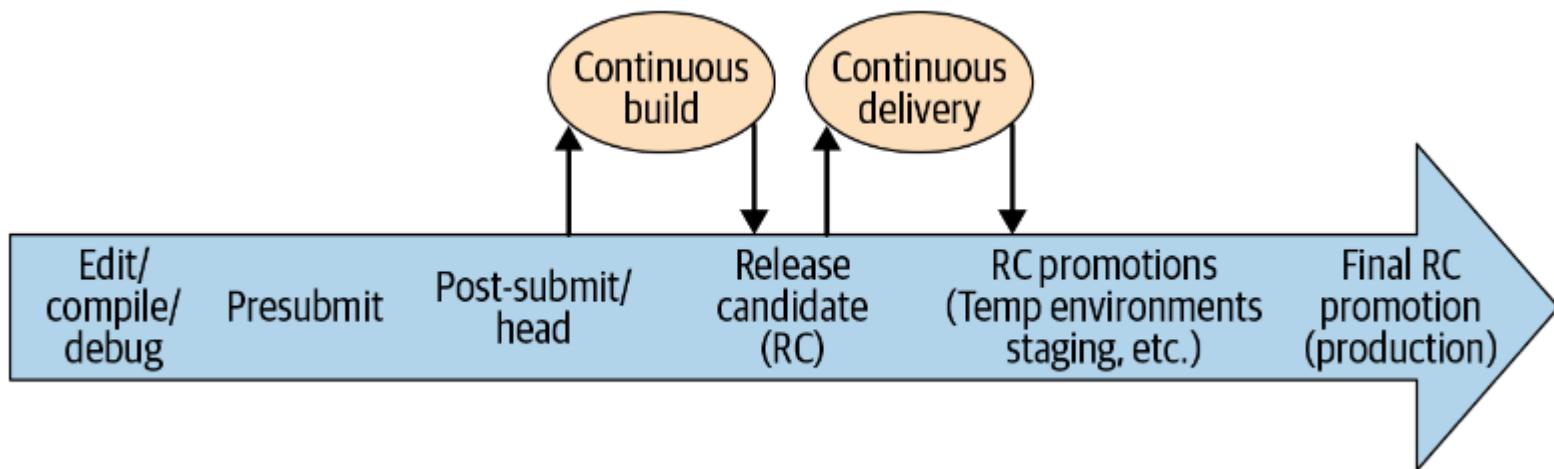

- CB integrates the latest code changes at HEAD
- CB runs automated build
- CB runs automated tests
- If the code passes all tests, CB marks it passing

“Breaking the build” or “failing the build” includes breaking compilation or breaking tests

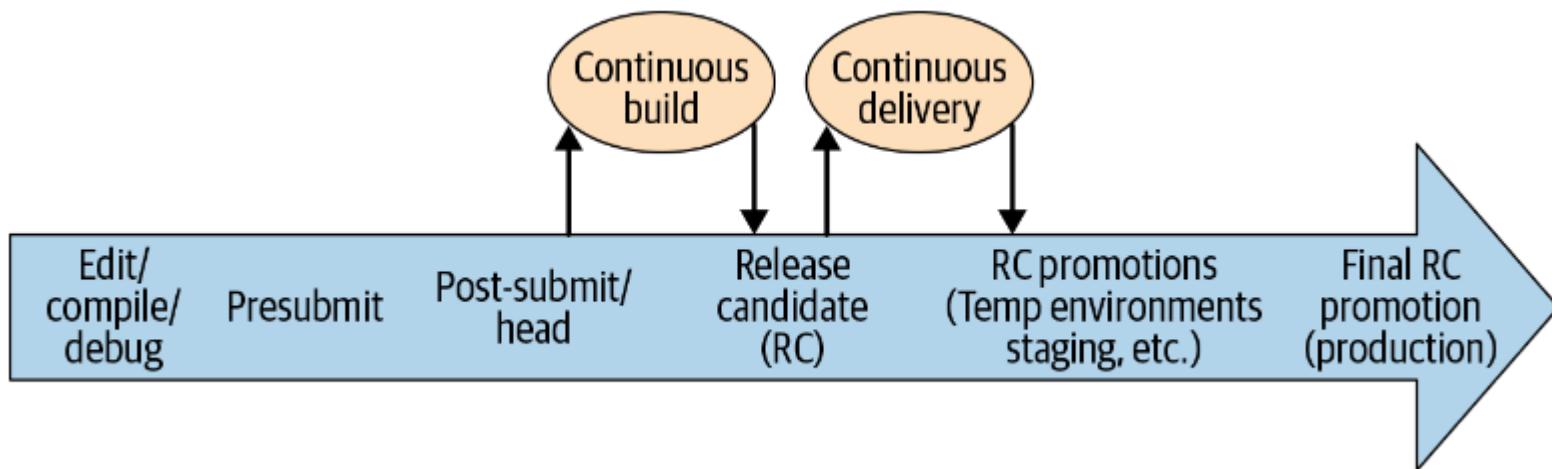

CONTINUOUS BUILD (CB)

- Release candidate (RC): a cohesive, deployable unit created by an automated process, assembled of code, configuration, and other dependencies that have passed the continuous build.

CONTINUOUS DELIVERY (CD)

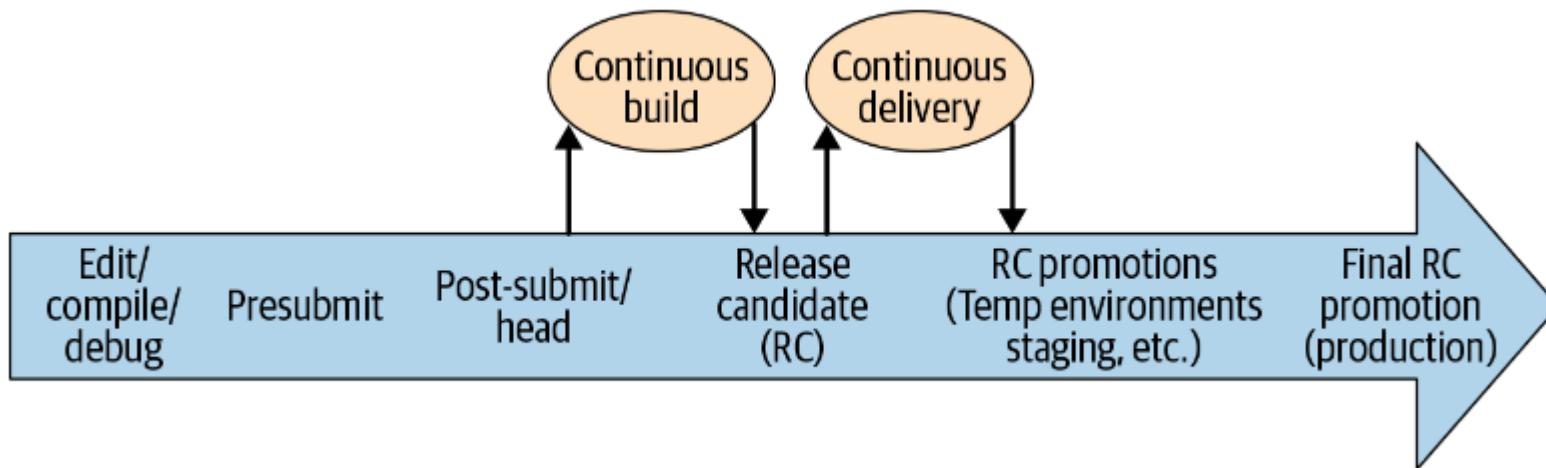

- CD: a continuous assembling of release candidates, followed by the promotion and testing of those candidates throughout a series of environments—sometimes reaching production and sometimes not.

CONTINUOUS TESTING

- Continuous testing is applied throughout the CI process
- Key objective: determining **when** to test **what**

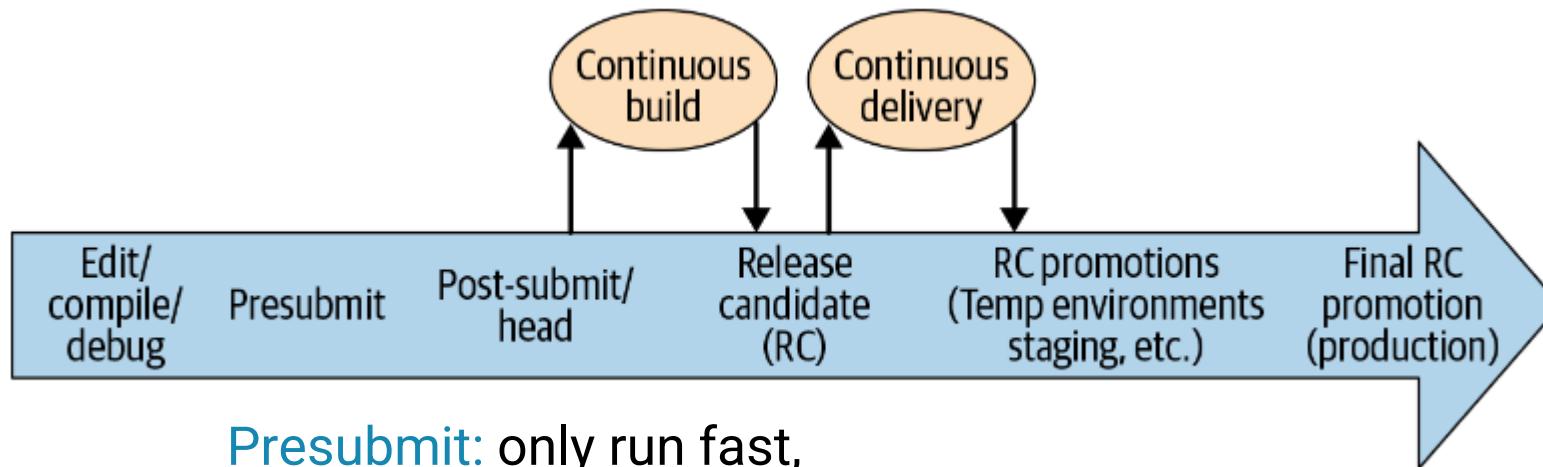

Why not just run all tests on presubmit?

CONTINUOUS TESTING - PRESUBMIT

Case study at Google

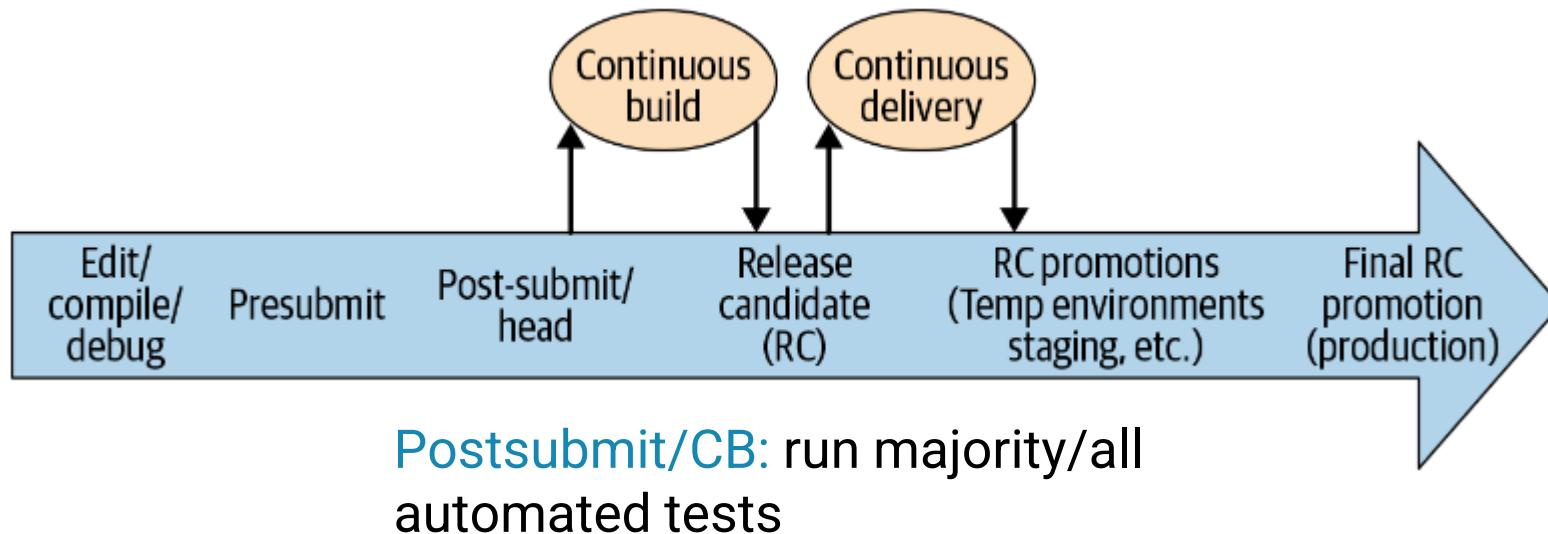

- Each team creates a **fast subset** of tests, often a project's unit tests, that can be run before a change is submitted and code reviewed (i.e., presubmit)
- Empirically, a change that passes the presubmit has a very high likelihood (95%+) of passing the rest of the tests

CONTINUOUS TESTING - POSTSUBMIT/CB

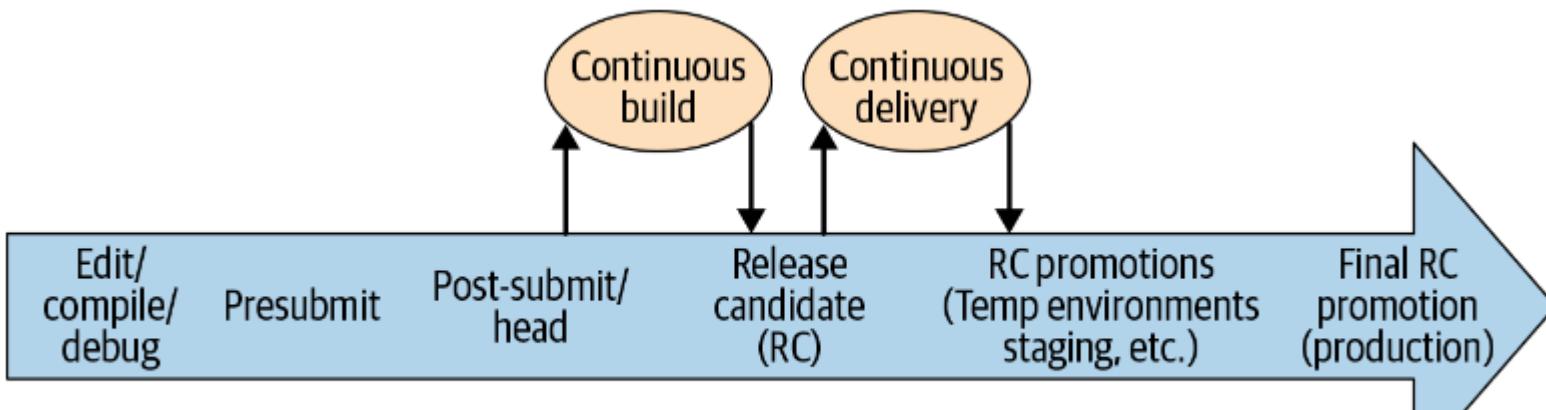

Case study at Google

- After a change has been submitted, the Test Automation Platform (TAP) run all potentially affected tests, including larger and slower tests
- When a change causes a test to fail on TAP, engineers decide whether to fix it or roll back (TAP enables automatic rollback on high-confidence cases)

CONTINUOUS TESTING - RC PROMOTION/CD

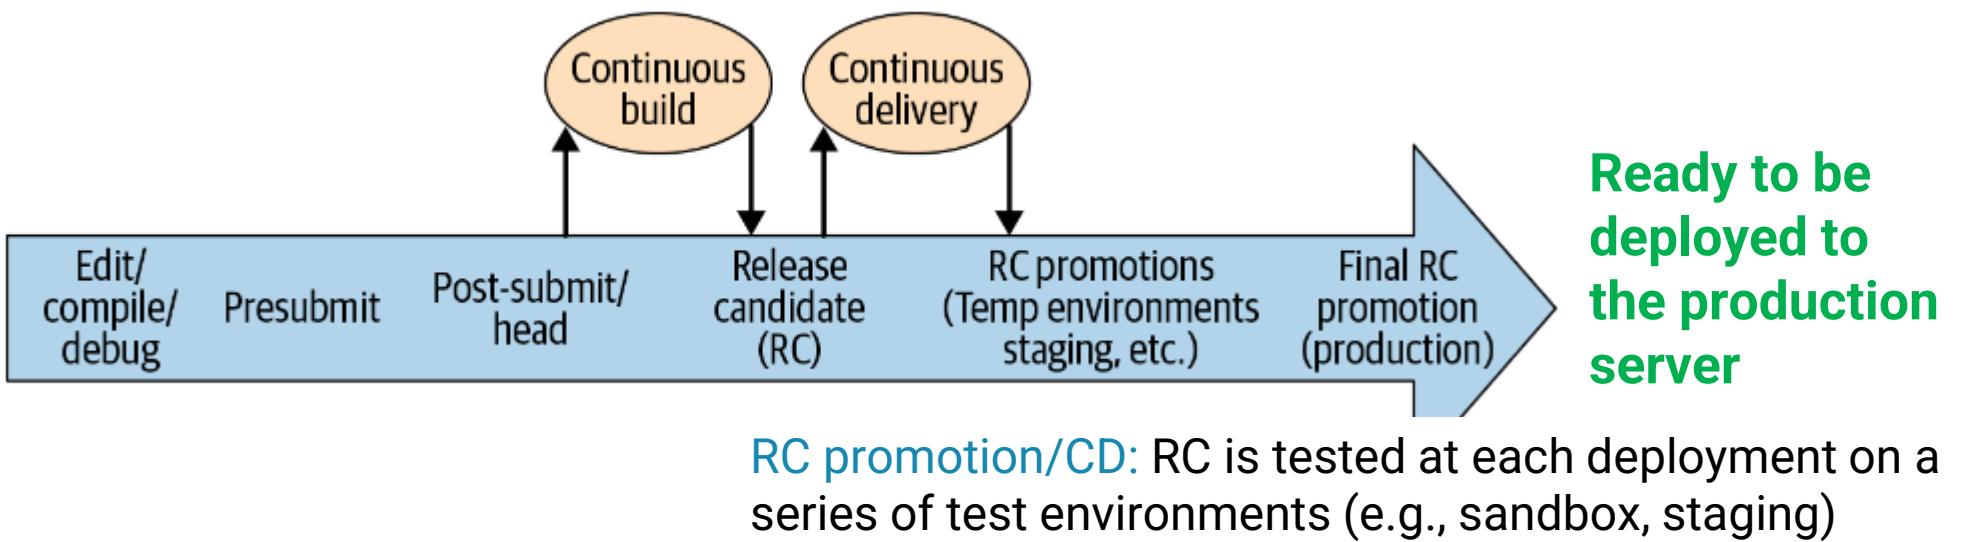

- **Staging (类生产环境)** is a test environment that exactly resembles a production environment
- It seeks to mirror an actual production environment as closely as possible and may connect to other production services and data, such as databases and servers.

RC promotion/CD: RC is tested at each deployment on a series of test environments (e.g., sandbox, staging)

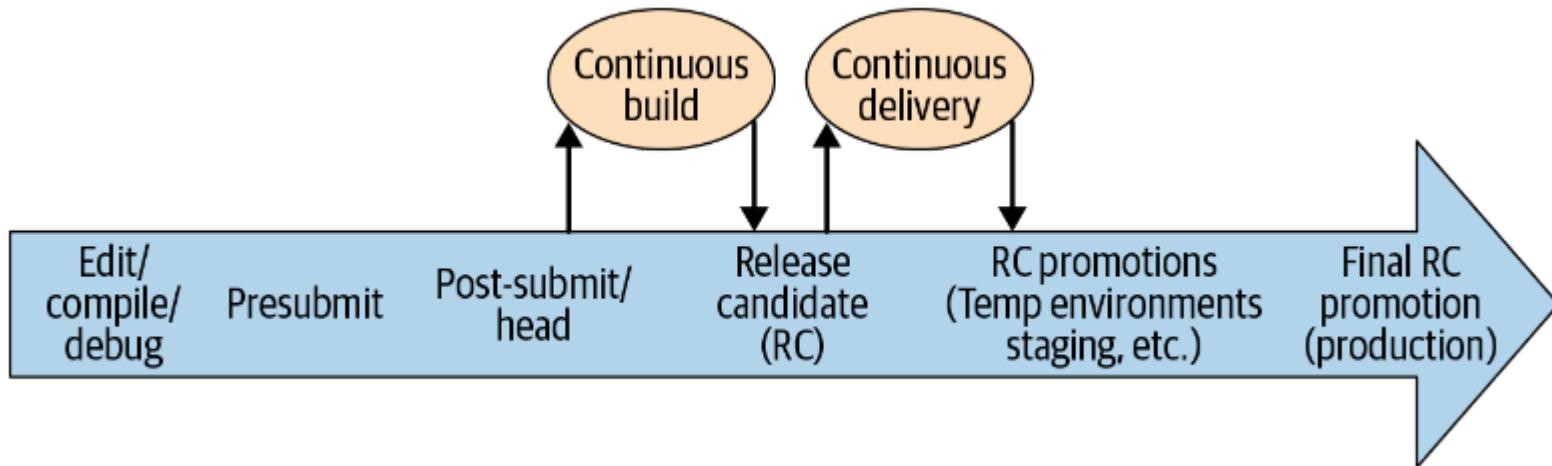

CONTINUOUS TESTING - RC PROMOTION/CD

- The primary use of a staging environment is to test all the **installation/configuration/migration** scripts and procedures before they're applied to a production environment.
- Another important use of staging is **performance testing**, particularly **load testing**

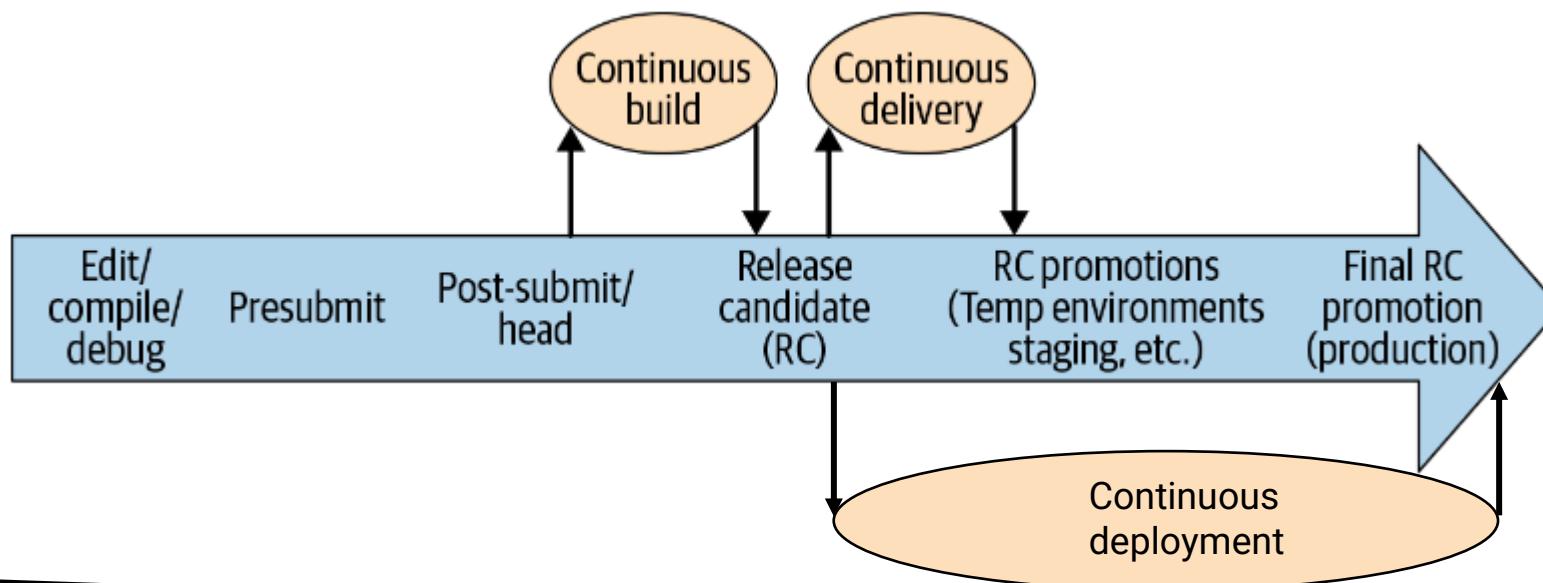

CONTINUOUS DEPLOYMENT

- CI/CD is (less often) referred to as continuous integration / continuous deployment
- Difference between continuous delivery and continuous deployment
- Continuous delivery automates deployment of a release to a staging or testing environment
 - Make sure that software changes are always in a **releasable state** (can be deployed at any time)
 - Decision of whether to deploy changes to production is left to the team (human intervention)

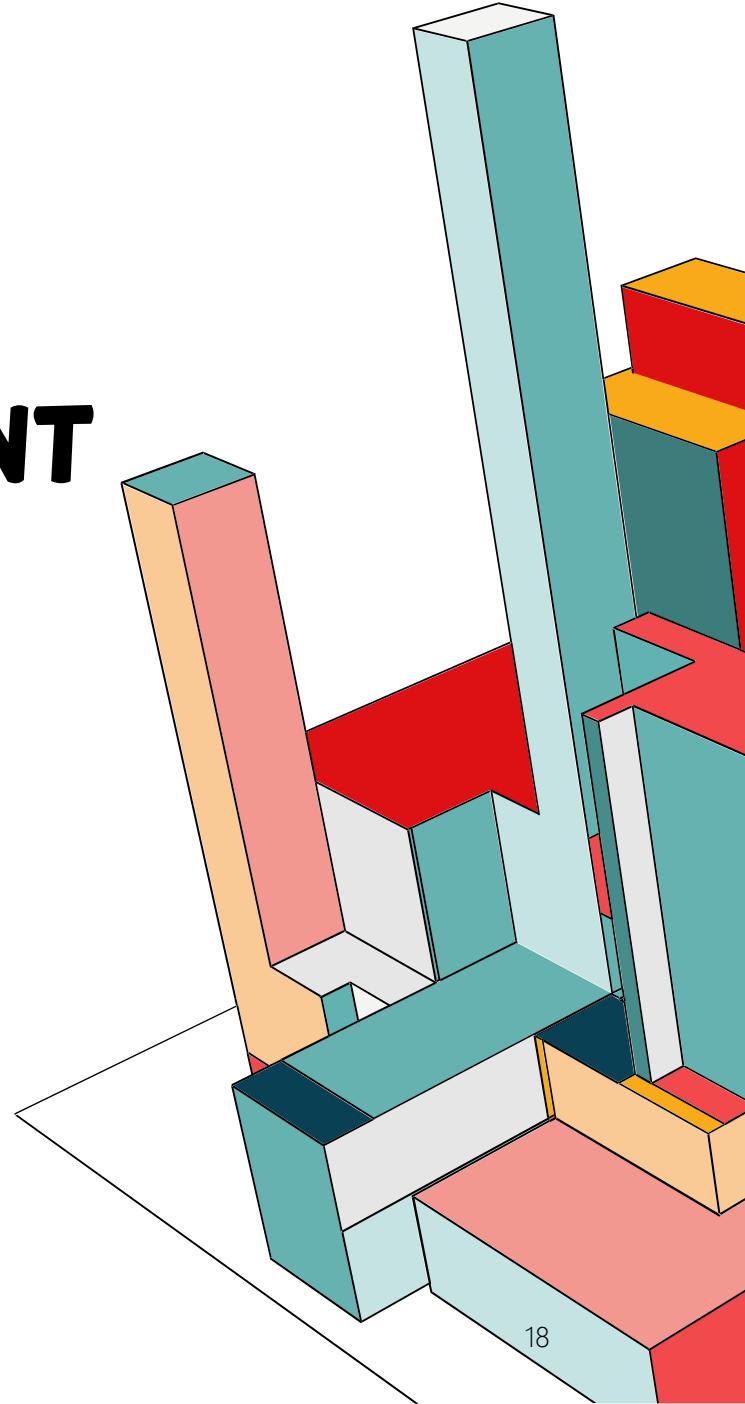

CONTINUOUS DEPLOYMENT

- CI/CD is (less often) referred to as continuous integration / continuous deployment
- Difference between continuous delivery and continuous deployment
- **Continuous deployment**: automates deployment of a release all the way to the production environment, no human intervention

RISKS OF CONTINUOUS DEPLOYMENT

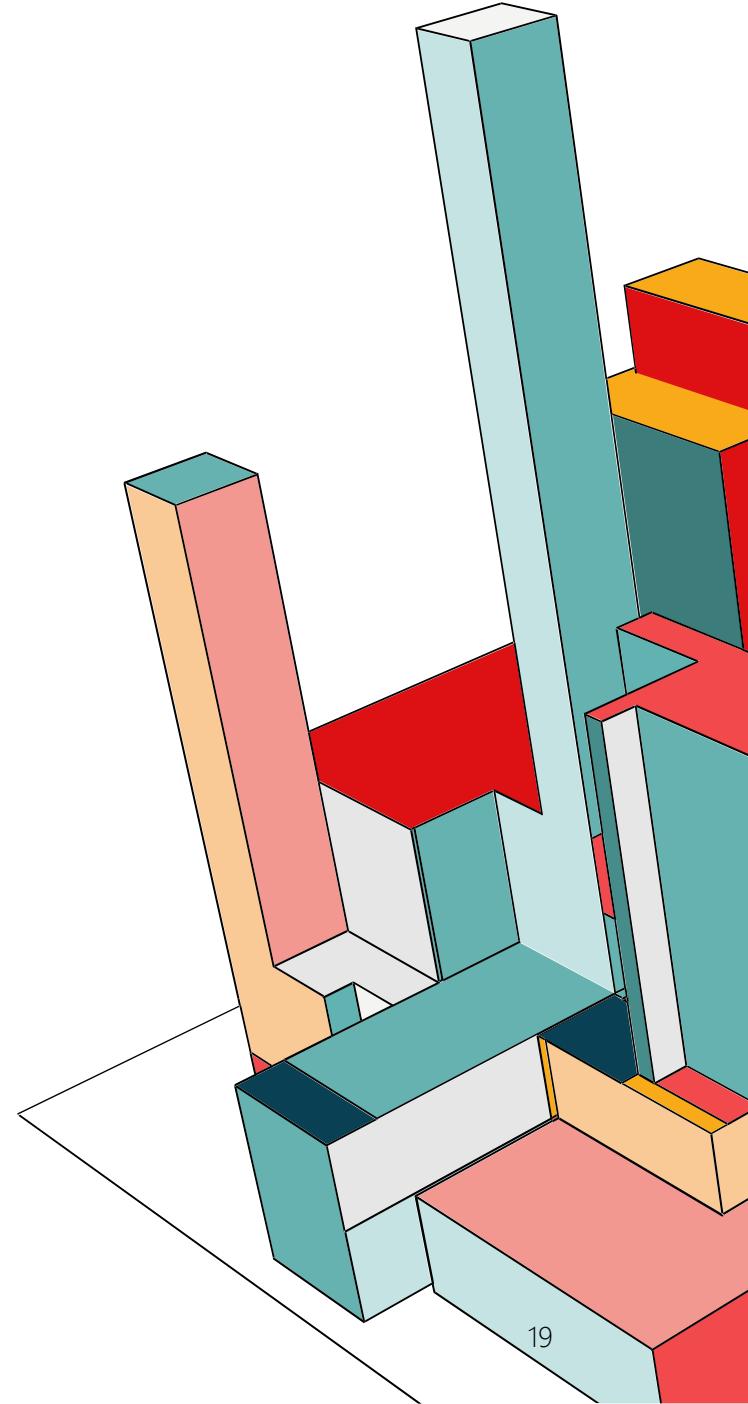

- New production version has problems and needed to be rolled back to previous versions
- Service is temporarily down during upgrading or rollback
-

DEPLOYMENT STRATEGIES

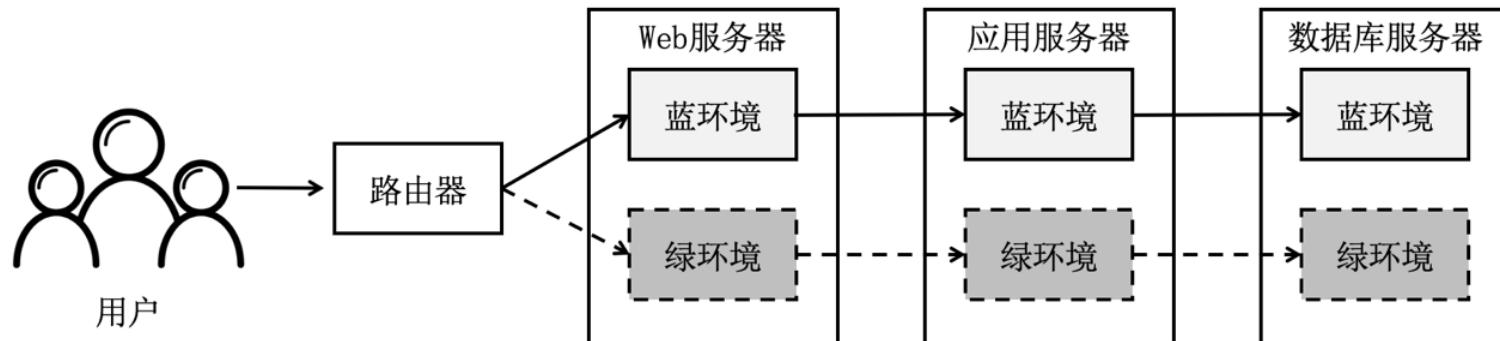

Goal: minimize the impact of new deployment on end users

- Blue-Green Deployment (蓝绿部署)
- Canary/Greyscale Release (金丝雀发布/灰度发布)

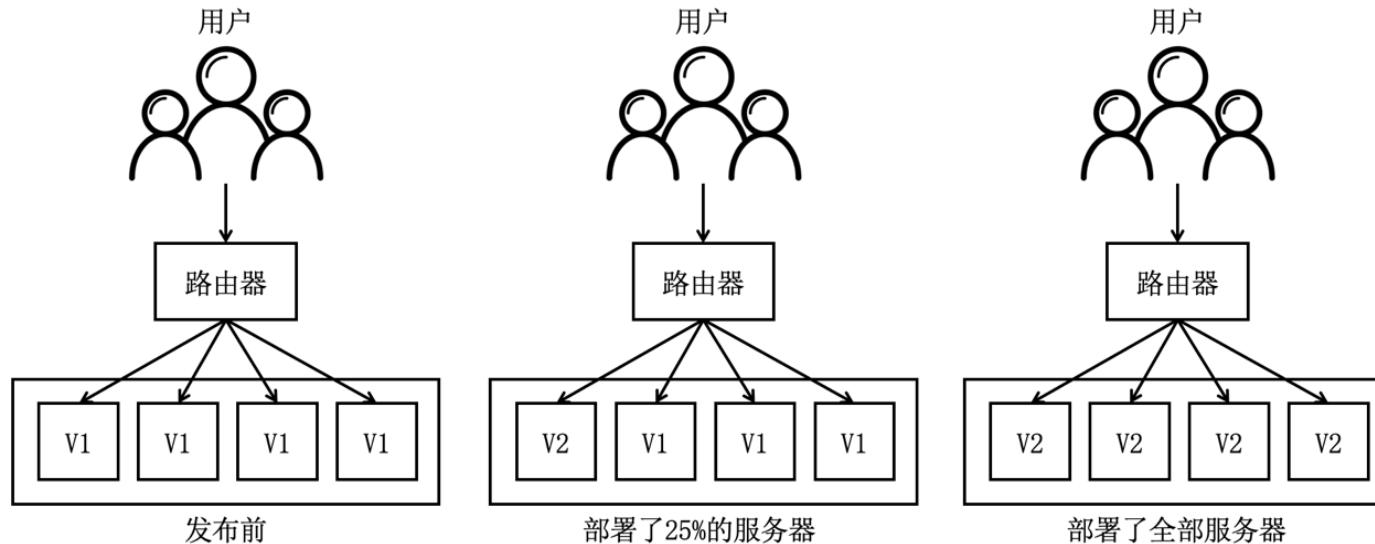

BLUE-GREEN DEPLOYMENT

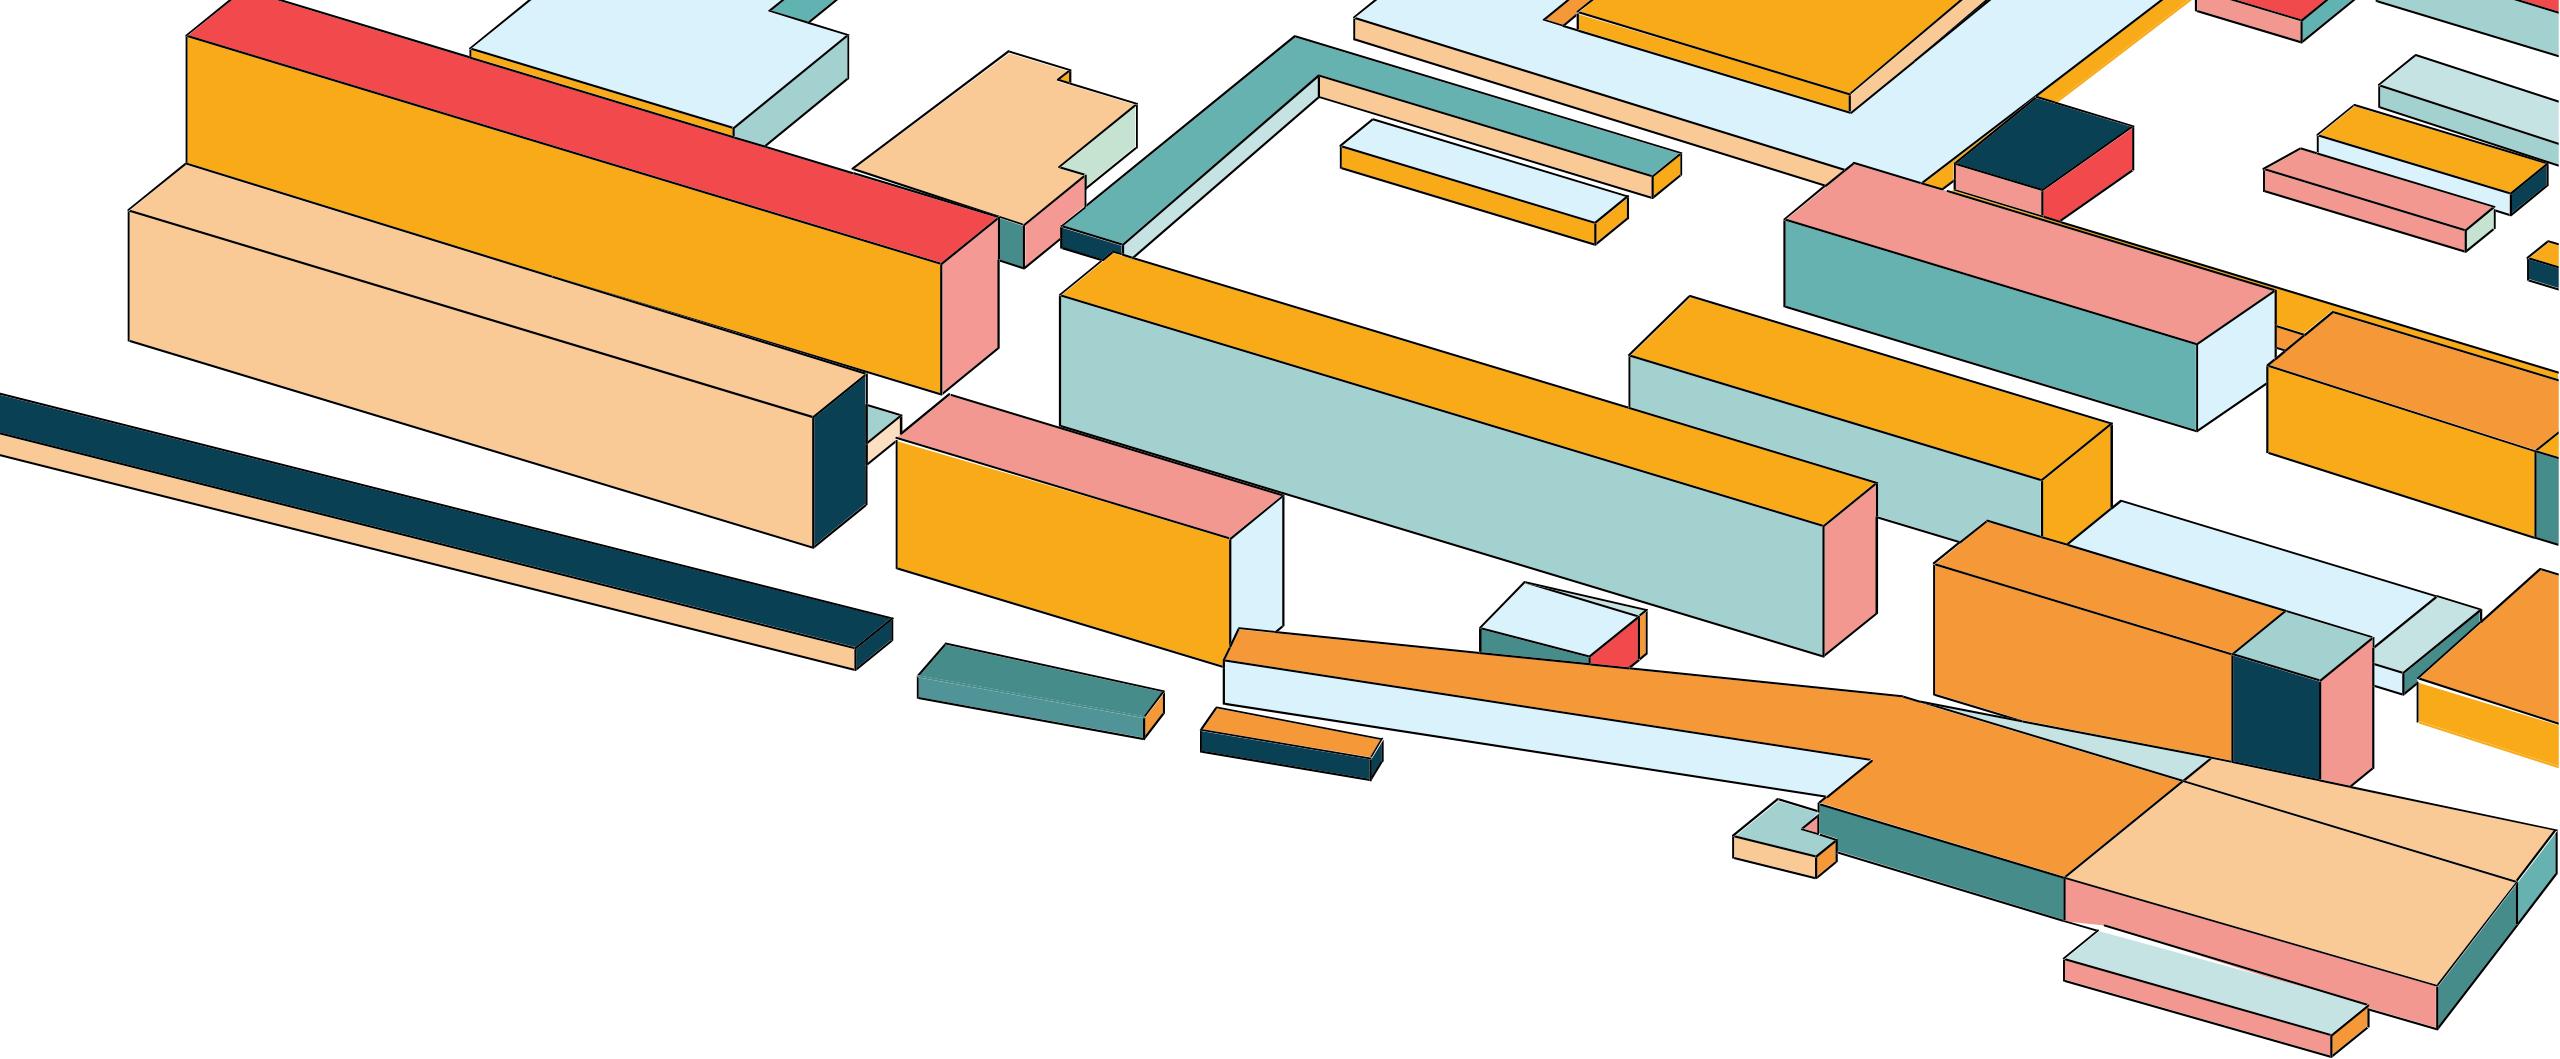

- A deployment strategy in which you create two separate, but identical environments.
- Blue environment is running the current/old application version
- Green environment is running the new application version.
- Once testing has been completed on the green environment, live application traffic is directed to the green environment.
- If error occurs, switch the traffic back to the blue environment

CANARY RELEASE (GREYSKALE RELEASE)

- A deployment strategy to reduce the risk of introducing a new software version in production
- Slowly rolling out the change to **a small subset of users (canary)** before rolling it out to the entire infrastructure and making it available to everybody.
- Once error occurs, simply stop the traffic to the server with new version

CLOUD NATIVE APPLICATIONS

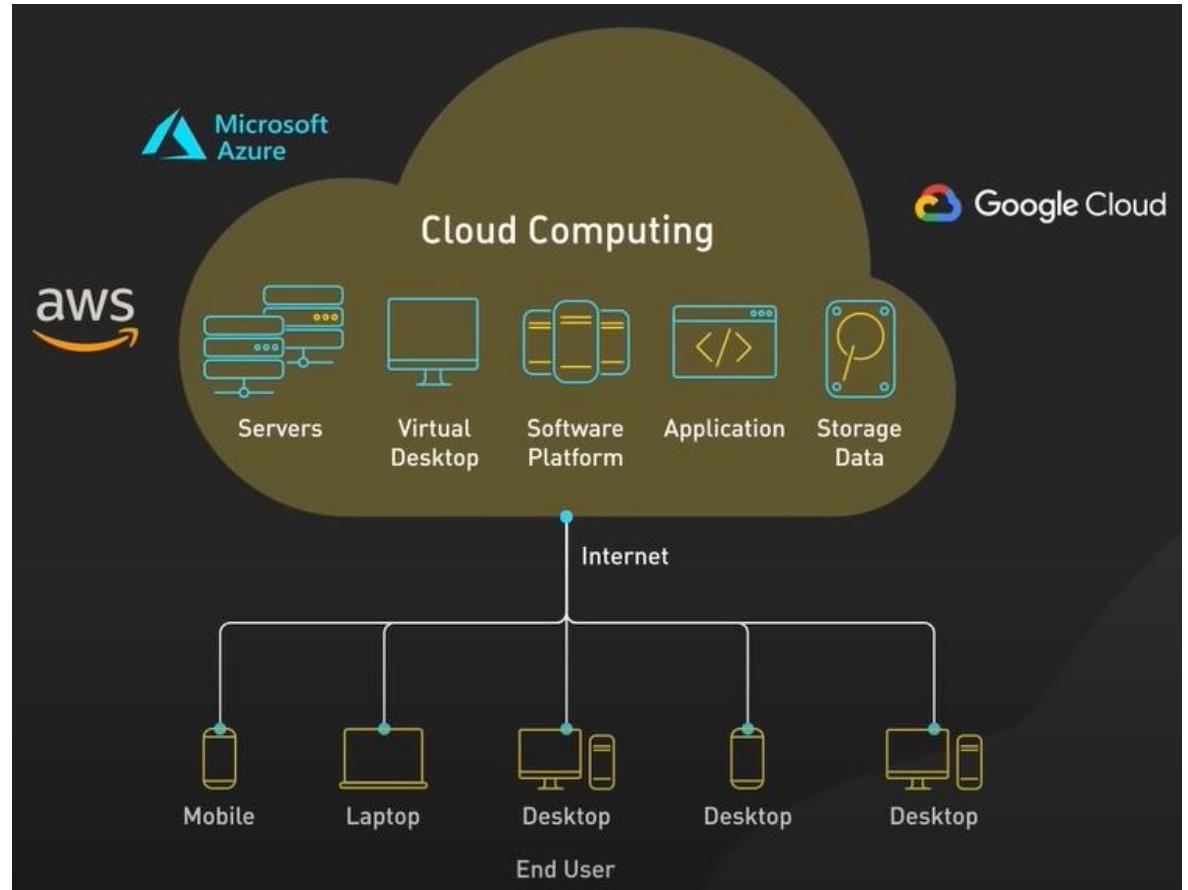

WHAT IS CLOUD NATIVE (云原生)?

<https://www.youtube.com/watch?v=p-88GN1WVs8>

CLOUD COMPUTING

Running applications on computing resources managed by cloud providers (e.g., aws), without having to purchase and manage hardware ourselves

<https://www.youtube.com/watch?v=p-88GN1WVs8>

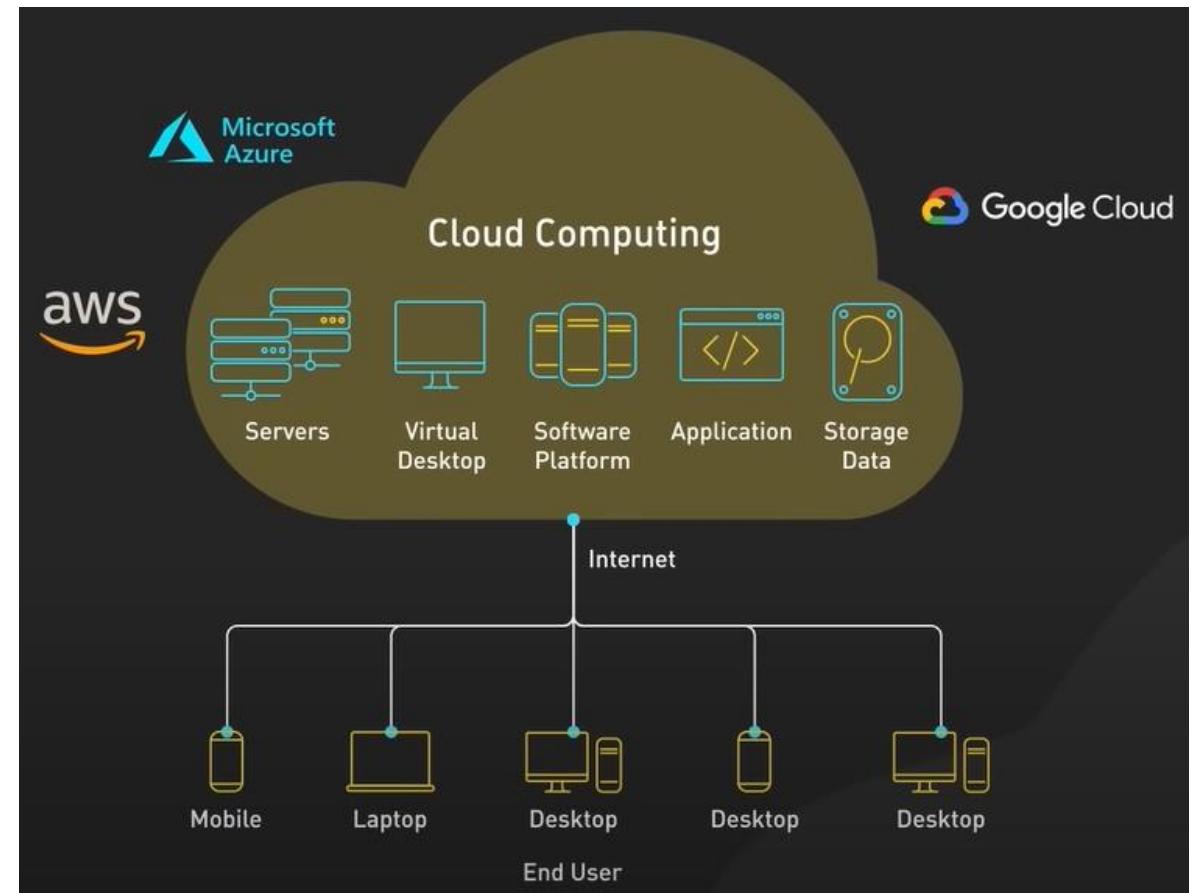

CLOUD COMPUTING

- Free the team from managing hardware infrastructure
- Fast to support new computing resources
- Scaling up is effortless

<https://www.youtube.com/watch?v=p-88GN1WVs8>

Still not cloud-native applications

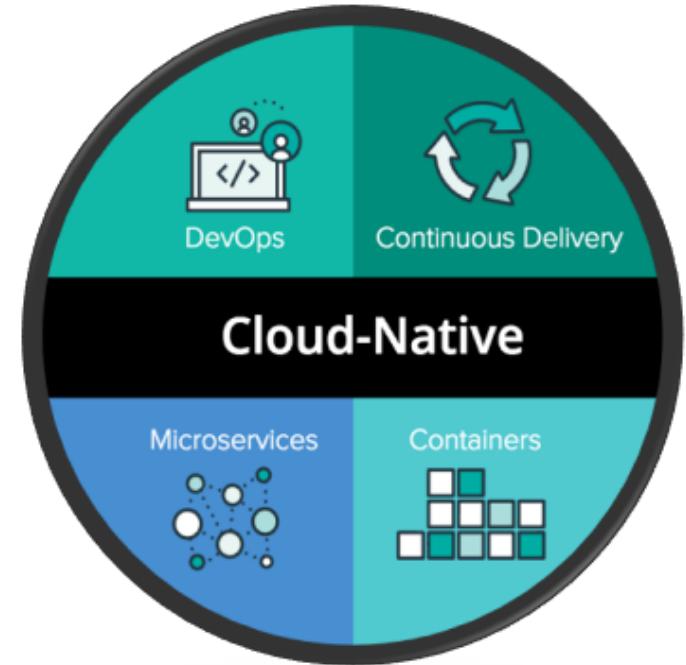

CLOUD NATIVE APPLICATIONS

Cloud native apps are designed and built to exploit the scale, elasticity, resiliency, and flexibility the cloud provides.

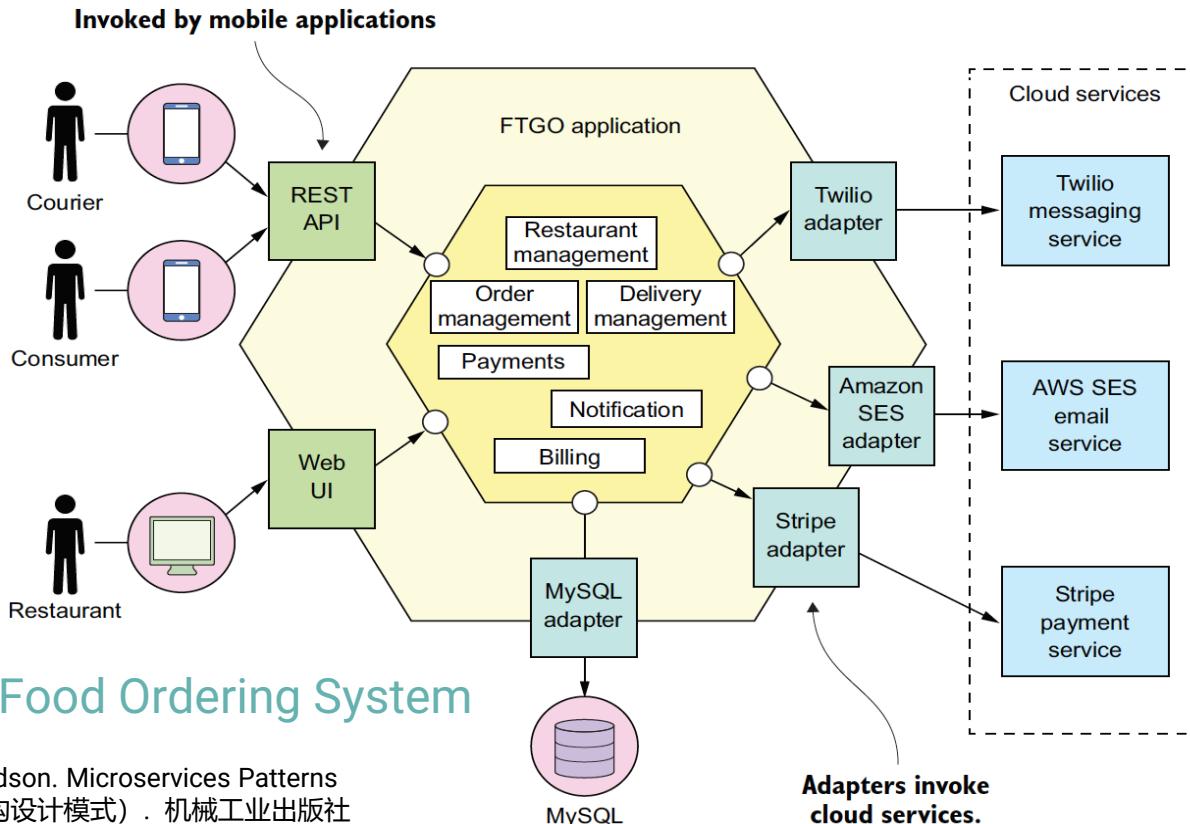

For an application to be considered as cloud-native, it should at least adopt these 4 approaches or technologies

- DevOps/Continuous Delivery
- Microservices
- Containers
- Cloud-native Open Standards

MICROSERVICES

Cloud-native applications consist of multiple small, interdependent services called microservices.

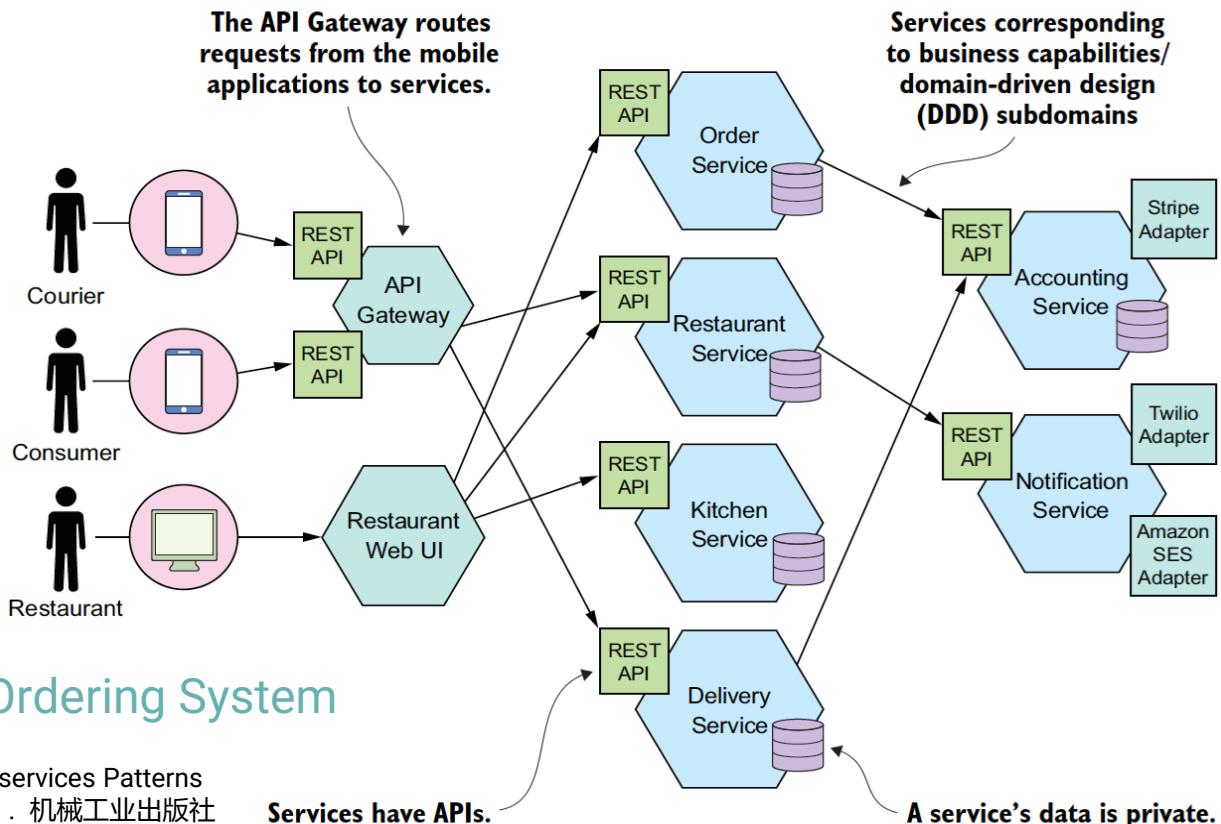

Monolithic architecture

- The whole application is packaged into a single executable
- Less flexible for large team/code base
- Difficult to scale, wasting deployment resources

MICROSERVICES

Cloud-native applications consist of multiple small, interdependent services called microservices.

Microservice Architecture

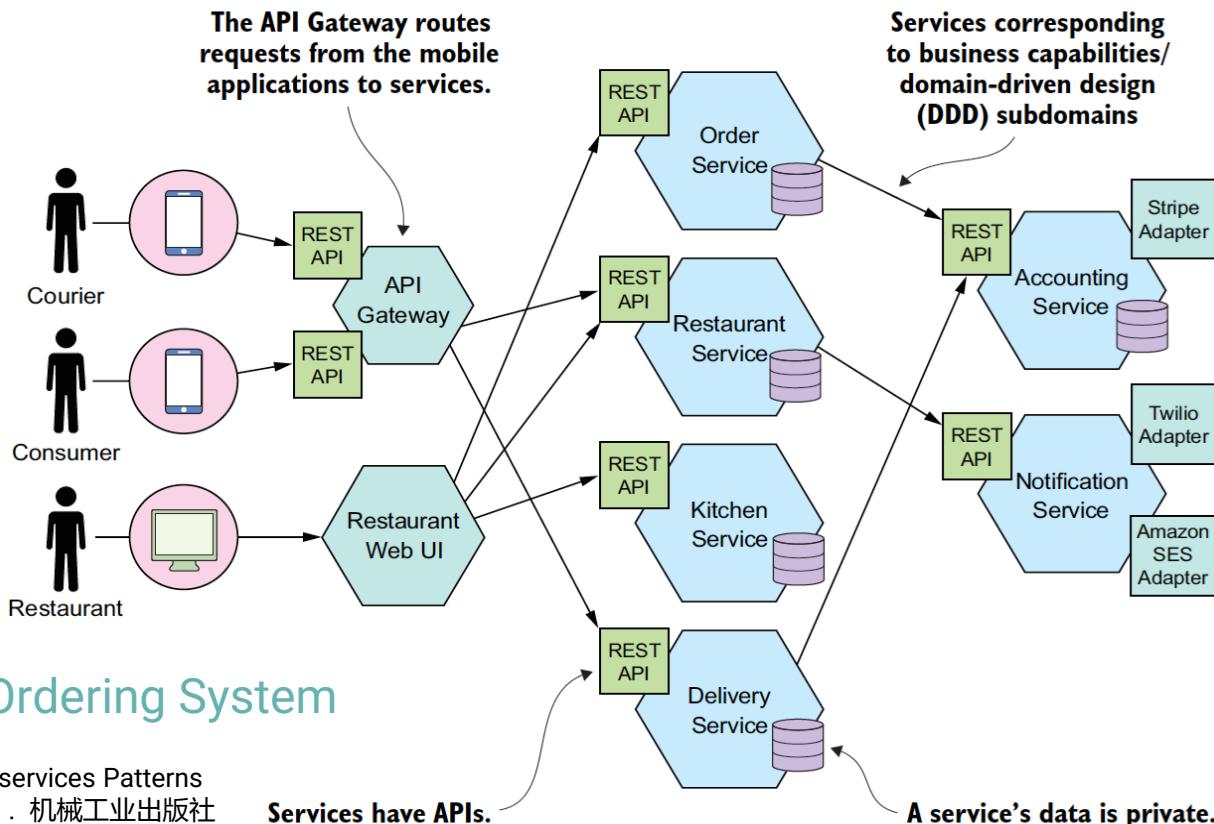

- Microservices allow a large application to be separated into smaller independent parts, with each part having its own responsibility
- Each service can be developed, managed, and deployed independently.

Online Food Ordering System

Chris Richardson. Microservices Patterns
(微服务架构设计模式) . 机械工业出版社

MICROSERVICES

Cloud-native applications consist of multiple small, interdependent services called microservices.

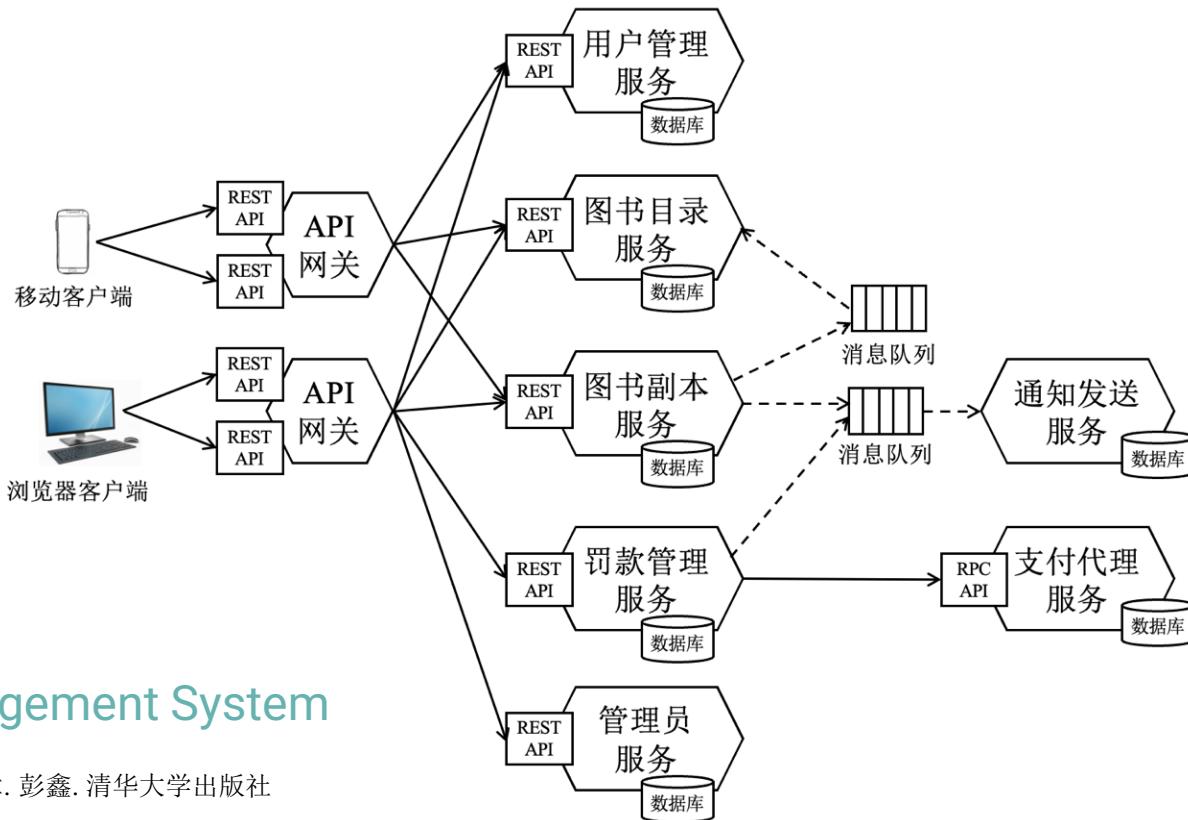

Microservice Architecture

- Services communicate with each other by using well-defined APIs (e.g., REST)
- We could scale only the required microservice

MICROSERVICES

Cloud-native applications consist of multiple small, interdependent services called microservices.

Microservice Architecture

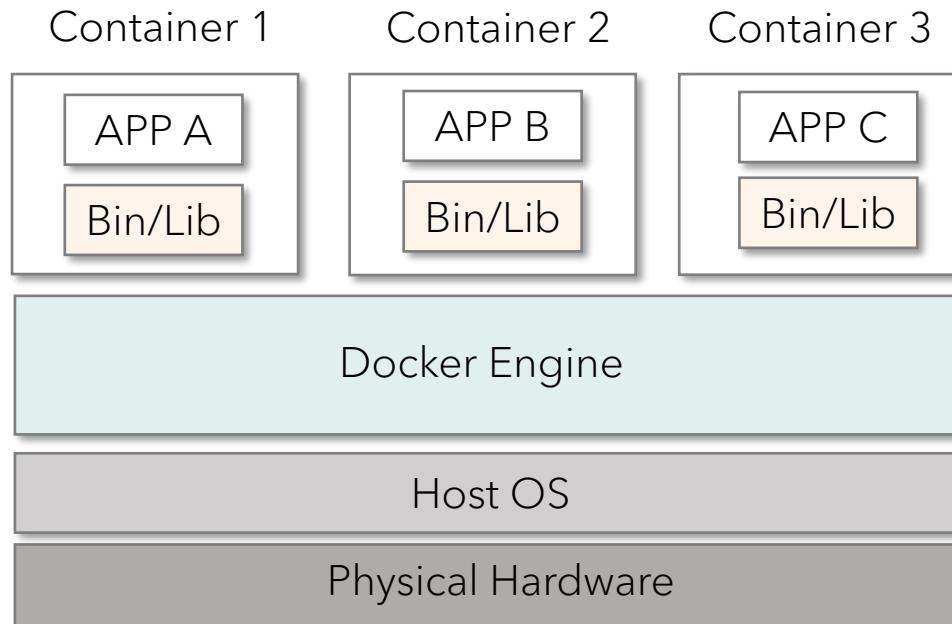

- Services communicate with each other by using well-defined APIs (e.g., REST)
- We could scale only the required microservice

Library Management System

现代软件工程基础,第7章. 彭鑫. 清华大学出版社

CONTAINERS

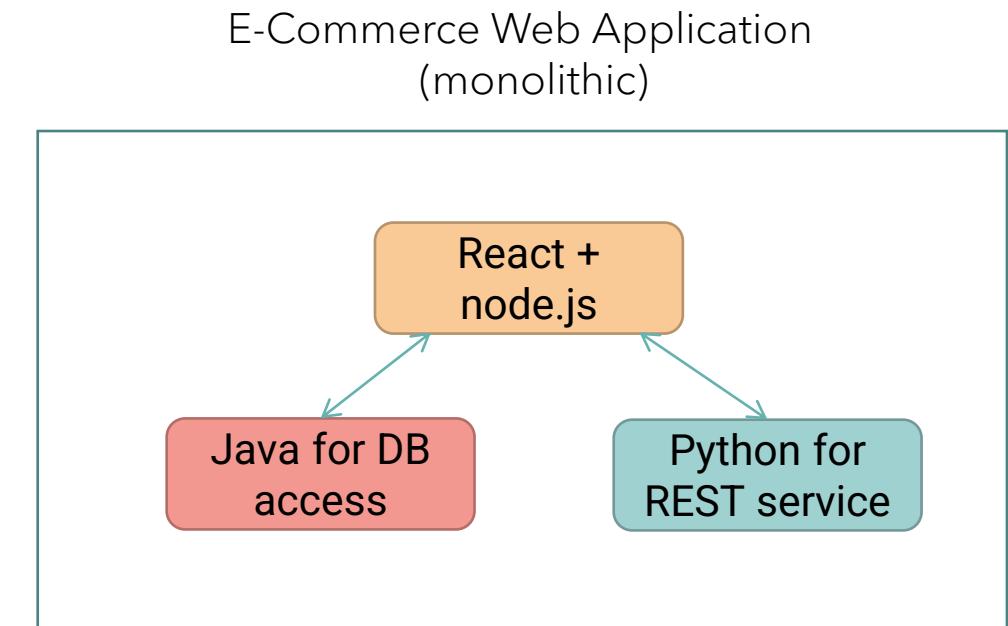

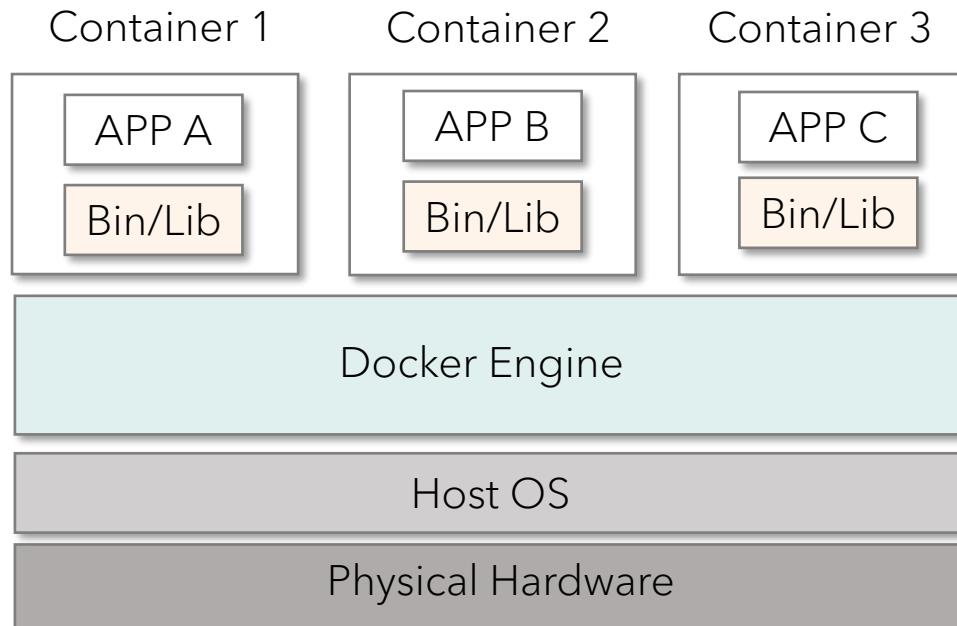

A container is a lightweight and portable unit of software that packages an application and its dependencies together in a single environment.

- A container consists of all the dependencies required to run an application, and isolates these dependencies from other containers on the same machine
- Developers can easily create, deploy, and run applications in a consistent and predictable manner across different servers or cloud platforms.

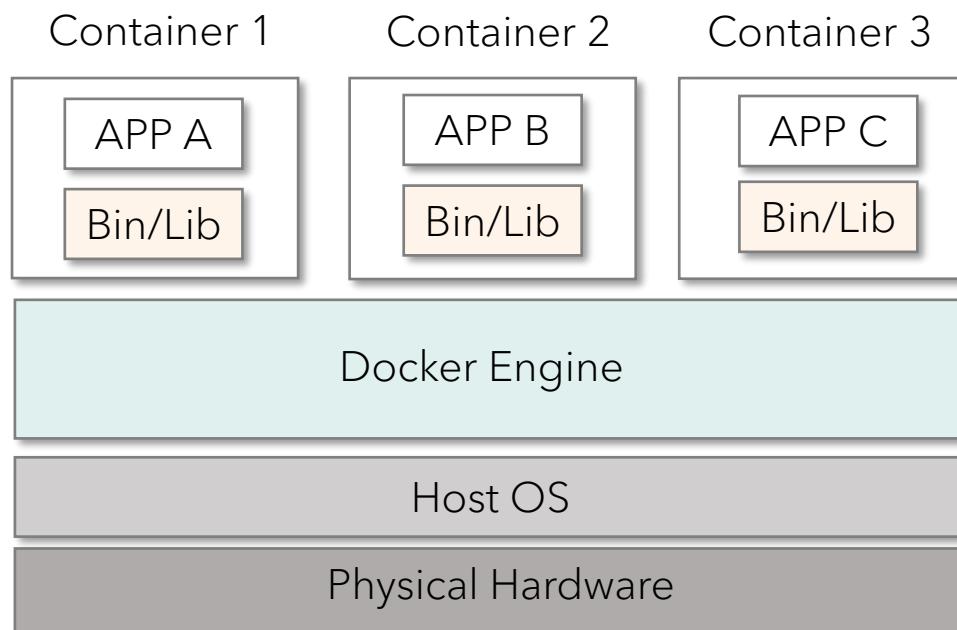

CONTAINERS

A container is a lightweight and portable unit of software that packages an application and its dependencies together in a single environment.

CONTAINERS

A container is a lightweight and portable unit of software that packages an application and its dependencies together in a single environment.

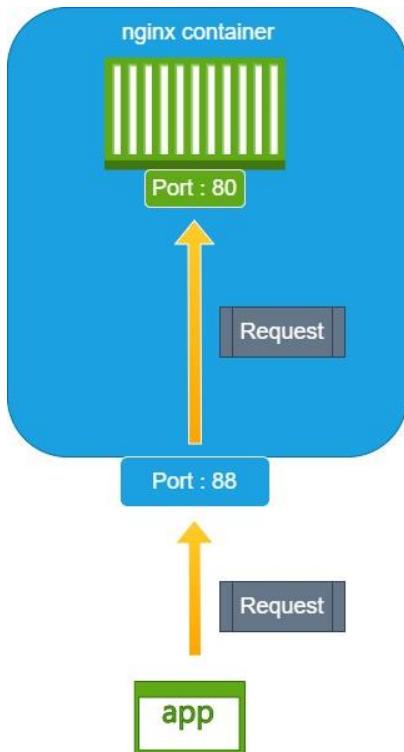

Container Communication

- Containers are assigned to unique IP addresses so that they could communicate with each other using standard network protocols (e.g., TCP/IP)

CONTAINERS

A container is a lightweight and portable unit of software that packages an application and its dependencies together in a single environment.

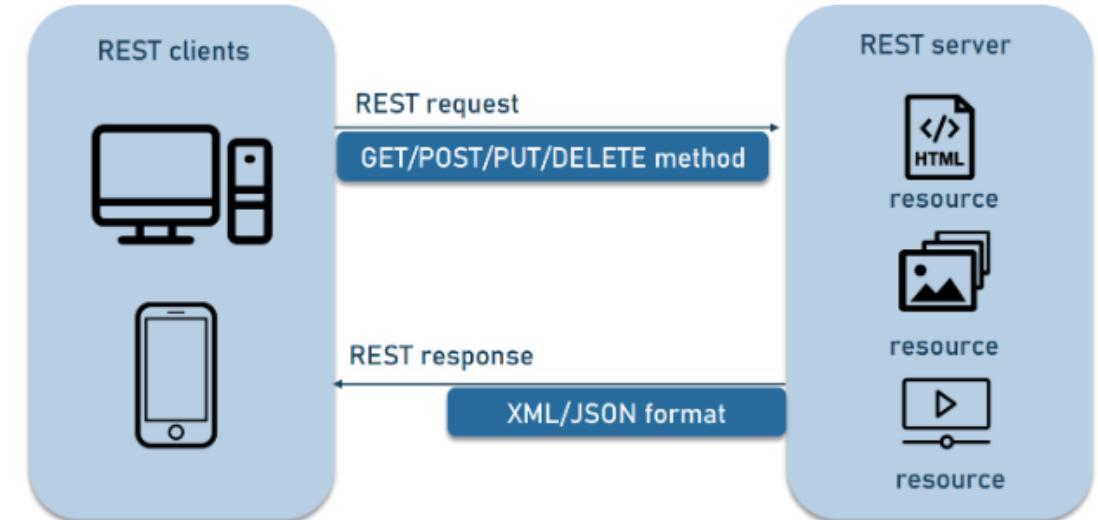

Container Communication

- Containers are assigned to unique IP addresses so that they could communicate with each other using standard network protocols (e.g., TCP/IP)
- Containers could expose **services** to the outside world by mapping container's port to the port on the host machine (port forwarding)

CONTAINERS - SERVICES

REST Services

- RESTful systems use HTTP verbs to manipulate resources identified by URIs (Uniform Resource Identifiers).
- RESTful APIs are stateless and cacheable, which makes them highly scalable and easy to manage.
- Clients can manipulate resources through simple and standardized interfaces.

<https://www.altexsoft.com/blog/rest-api-design/>

CONTAINERS - SERVICES

REST Services

- RESTful systems use HTTP verbs to manipulate resources identified by URIs (Uniform Resource Identifiers).
- RESTful APIs are stateless and cacheable, which makes them highly scalable and easy to manage.
- Clients can manipulate resources through simple and standardized interfaces.

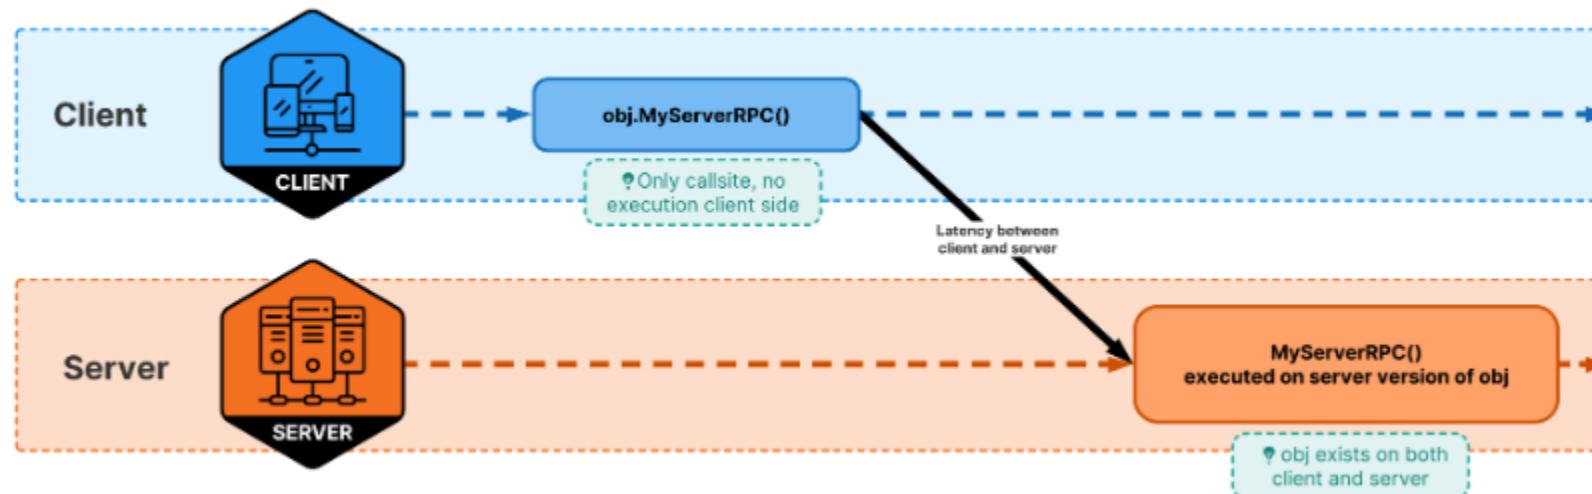

Sample API endpoints for an E-commerce application

GET /products - returns a list of all products
GET /products/{id} - returns details of a specific product
POST /orders - creates a new order
GET /orders/{id} - returns details of a specific order
POST /customers - creates a new customer
GET /customers/{id} - returns details of a specific customer

CONTAINERS - SERVICES

RPC Services

- RPC is a mechanism for invoking a function or method on a remote server, and receiving the results back.
- When calling an RPC, you call a method remotely on an object that can be anywhere in the world (i.e., RPC methods execute on a different machine)

<https://docs-multiplayer.unity3d.com/netcode/current/advanced-topics/messaging-system/index.html>

DOCKER

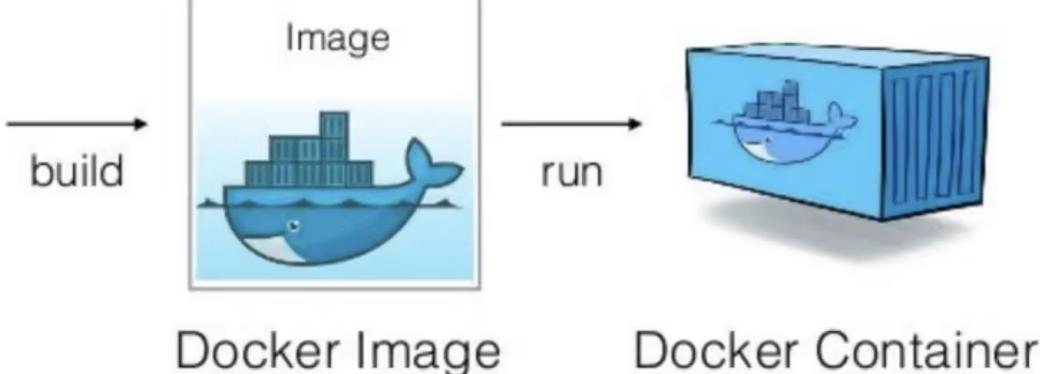

Docker is one of the most popular platforms for building, deploying, and managing containers

Docker image (镜像): a read-only **template** that acts as a set of instructions to create a container.

Dockerfile: a script that defines the instructions for building the image

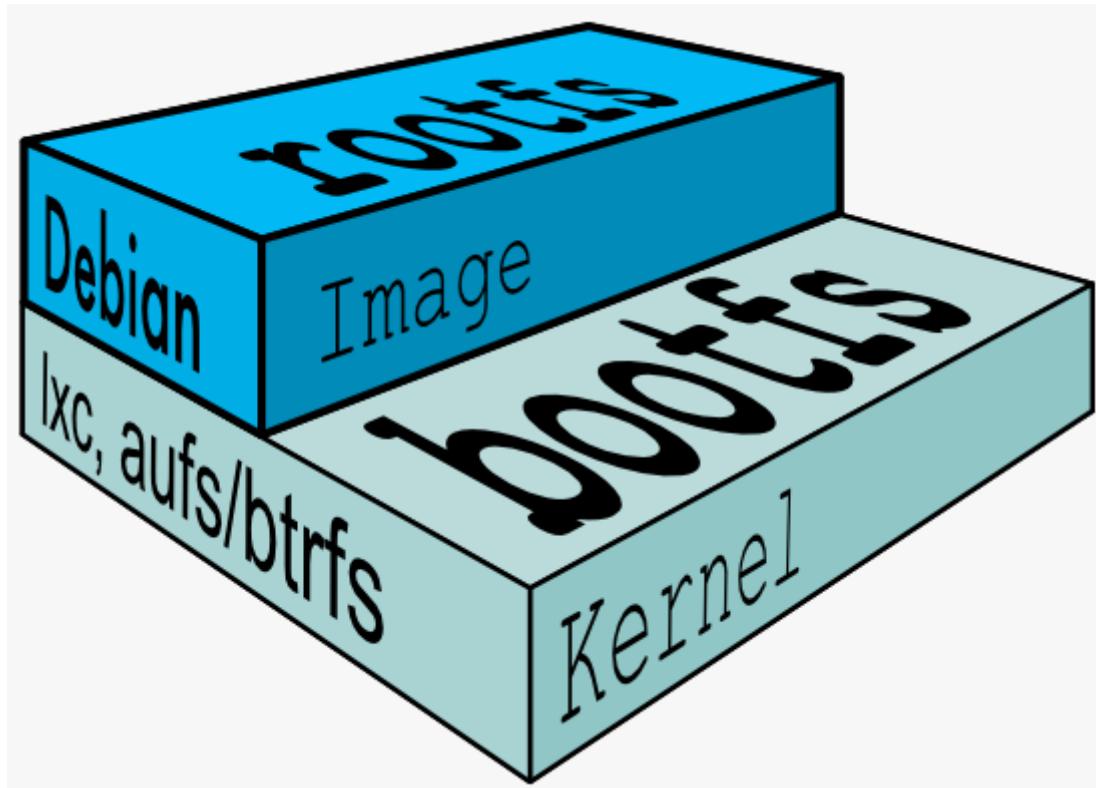

Dockerfile

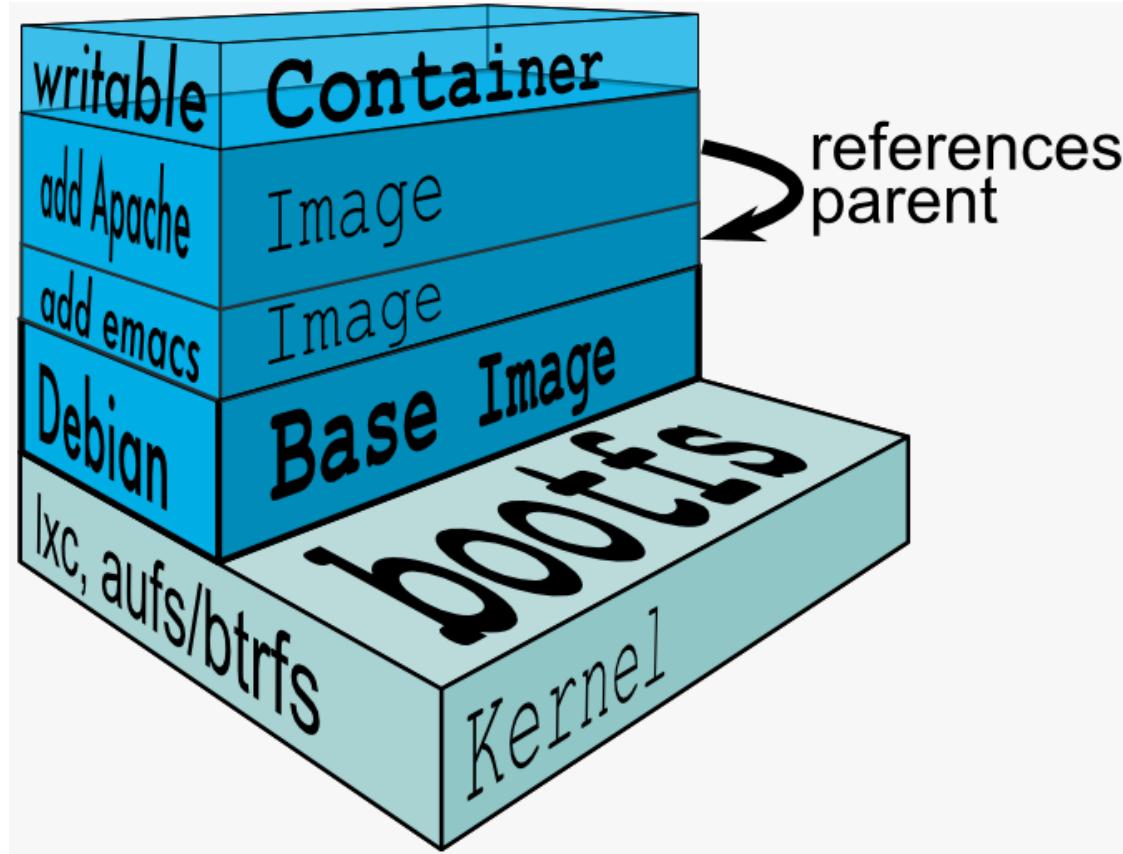

Docker container: a **running instance** of a Docker image

DOCKER IMAGES

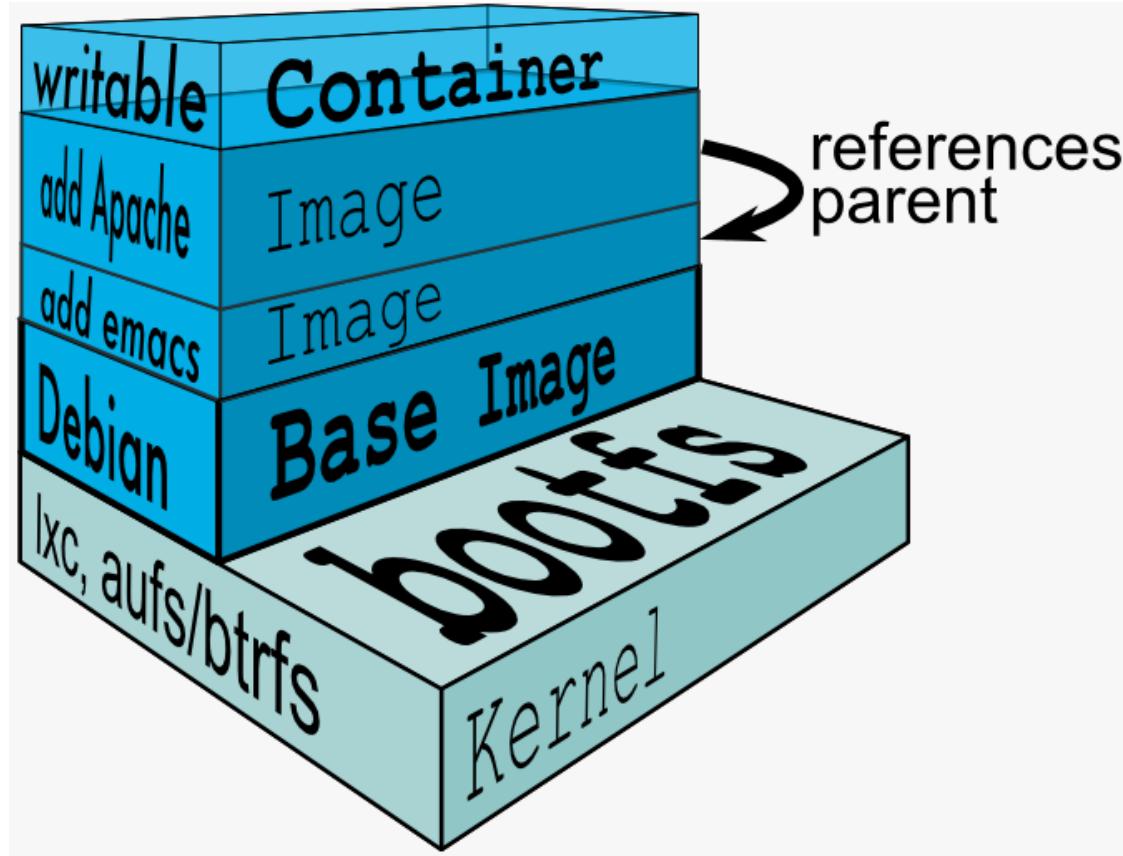

- Docker images consist of many layers. Each layer is built on top of another layer to form a series of intermediate images
- Kernel: Host machine's kernel
- Base image:
 - Different Linux distribution, e.g., Debian, Ubuntu
 - Various pre-installed software images, e.g., OpenJDK
 - Or a blank image with nothing included

DOCKER IMAGES

- Images (**read-only**) can be layered on top of one another, specified by Dockerfile
- Each time Docker launches a container from an image, it adds a thin **writable** layer, known as the container layer, which stores all changes to the container throughout its runtime.

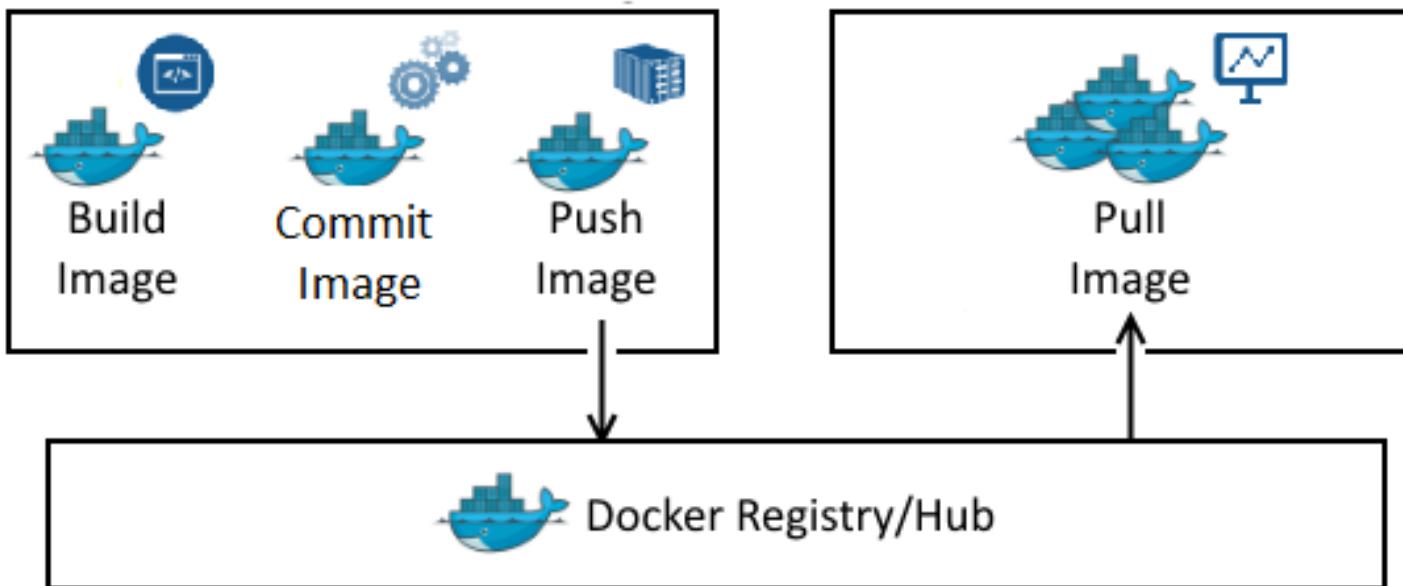

DOCKER IMAGES

- The top layer has read-write permissions, and all the remaining layers have read-only permissions
- Several containers may share access to the same underlying level of a Docker image, but write the changes locally and uniquely to each other

DOCKER IMAGES

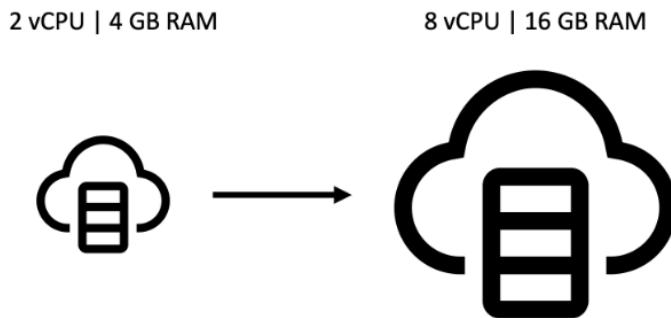

Docker image could be shared as we did for source code version control

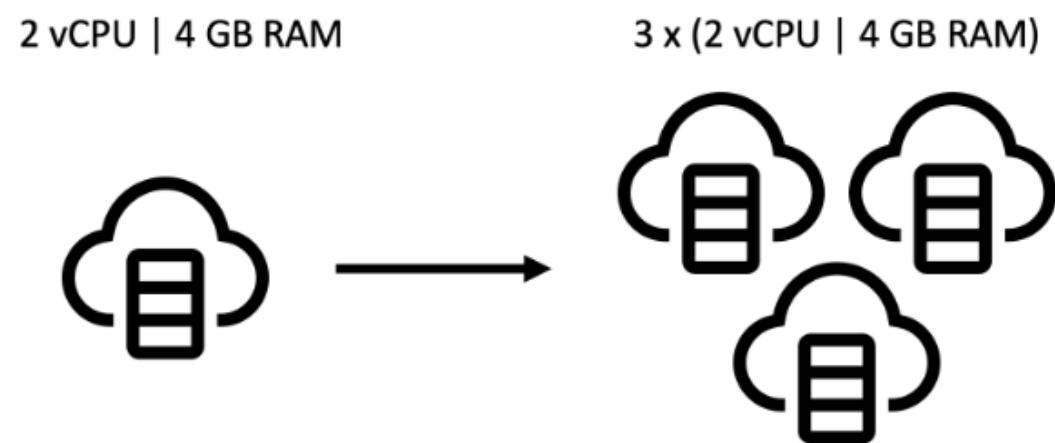

SCALE

Our application becomes much more popular. Many more users start to use our application

Scale up (Vertical scaling)

Scale out (Horizontal scaling)

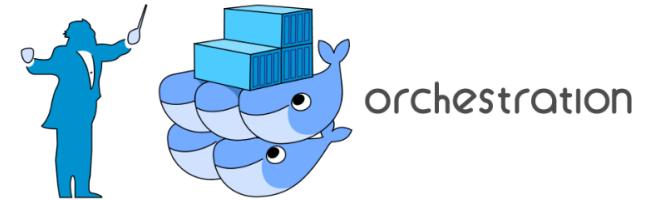

<https://developer.ibm.com/articles/scale-up-and-scale-out-vms-vs-containers/>

SCALE OUT - COMPLEXITIES

- **Load Balancing:** With more servers added, it's important to distribute incoming traffic across these servers to ensure that the load is evenly distributed
- **Configuration:** each new server or node needs to be configured properly to work with the rest of the infrastructure (e.g., network config, security config). As the number of servers grows, the complexity of configuring and managing them can increase.
- **Monitoring/Troubleshooting:** With more servers in the infrastructure, it becomes more difficult to monitor the system and identify issues.
- **Maintenance:** With more servers, there is more hardware and software that needs to be maintained and updated, which increases the workload and complexity of managing the infrastructure.

CONTAINER ORCHESTRATION

Use container orchestration to **automate and manage** tasks such as:

- Deployment
- Configuration
- Scheduling
- Resource allocation
- Container availability
- Load balancing and traffic routing
- Scaling or removing containers based on balancing workloads across your infrastructure
- Monitoring container health
- Keeping interactions between containers secure

CONTAINER ORCHESTRATION TOOLS

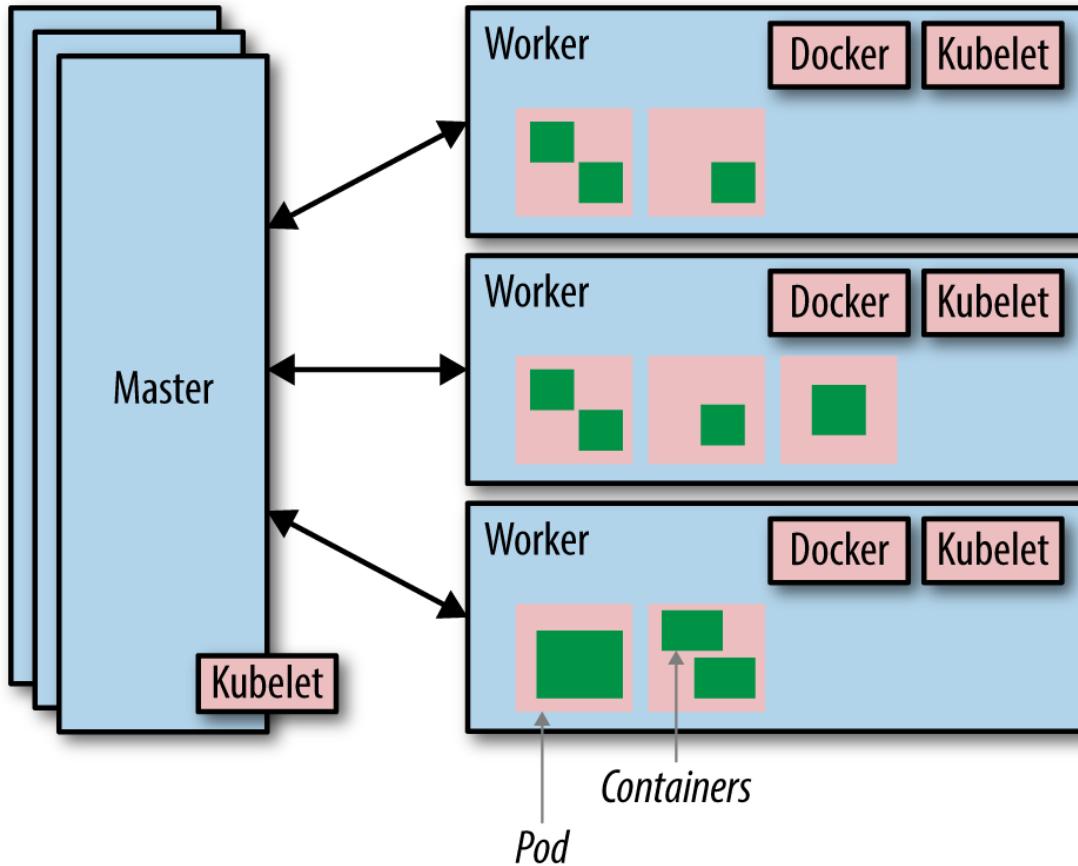

Docker Swarm and Kubernetes (K8s) are both container orchestration tools that allow for the management and deployment of containerized applications **at scale**

kubernetes

KUBERNETES ARCHITECTURE

<https://enabling-cloud.github.io/kubernetes-learning/>

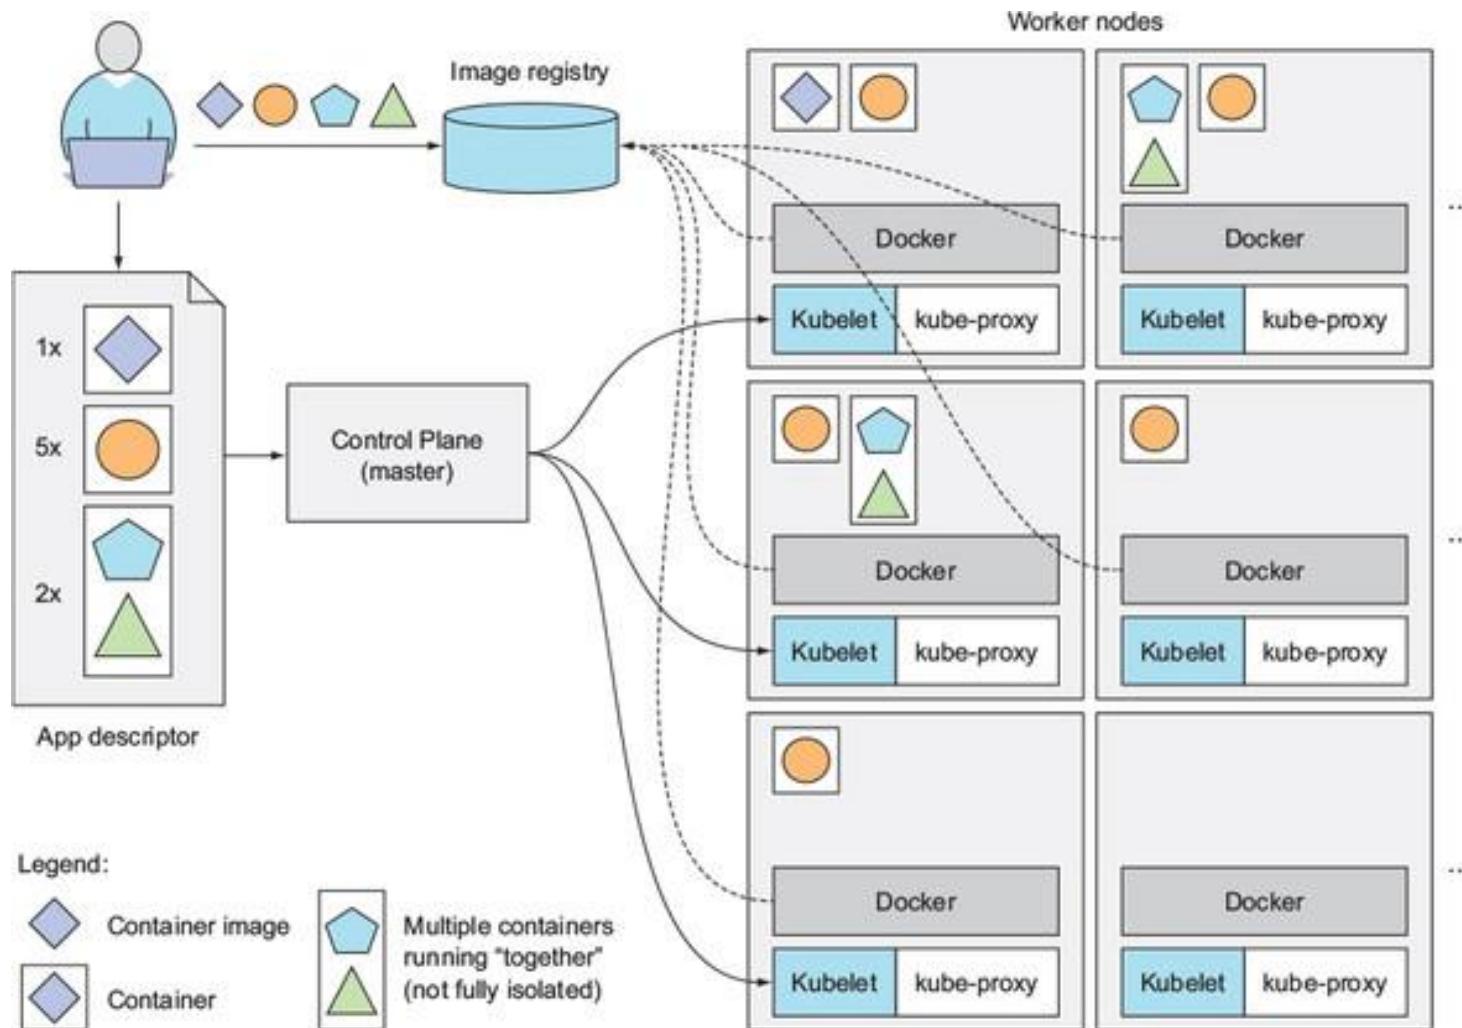

Cluster: A control plane and one or more compute machines, or worker nodes.

- **Control plane (master):** The collection of processes that control k8s nodes. This is where all task assignments originate.
- **Worker nodes:** Worker nodes within the k8s cluster are used to run containerized applications
 - **Kubelet:** This service runs on nodes and reads the container manifests and ensures the defined containers are started and running.=
 - **Pod:** A group of one or more containers deployed to a single node. All containers in a pod share an IP address, hostname, and other resources.

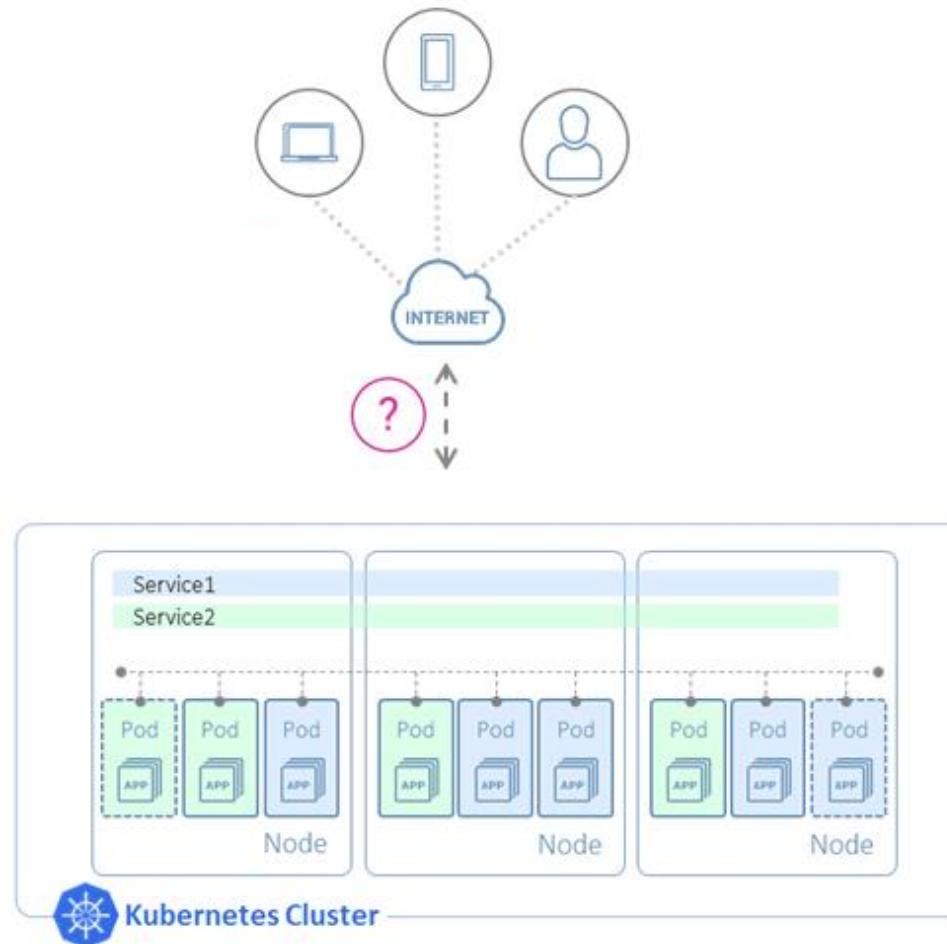

KUBERNETES ARCHITECTURE

<https://enabling-cloud.github.io/kubernetes-learning/>

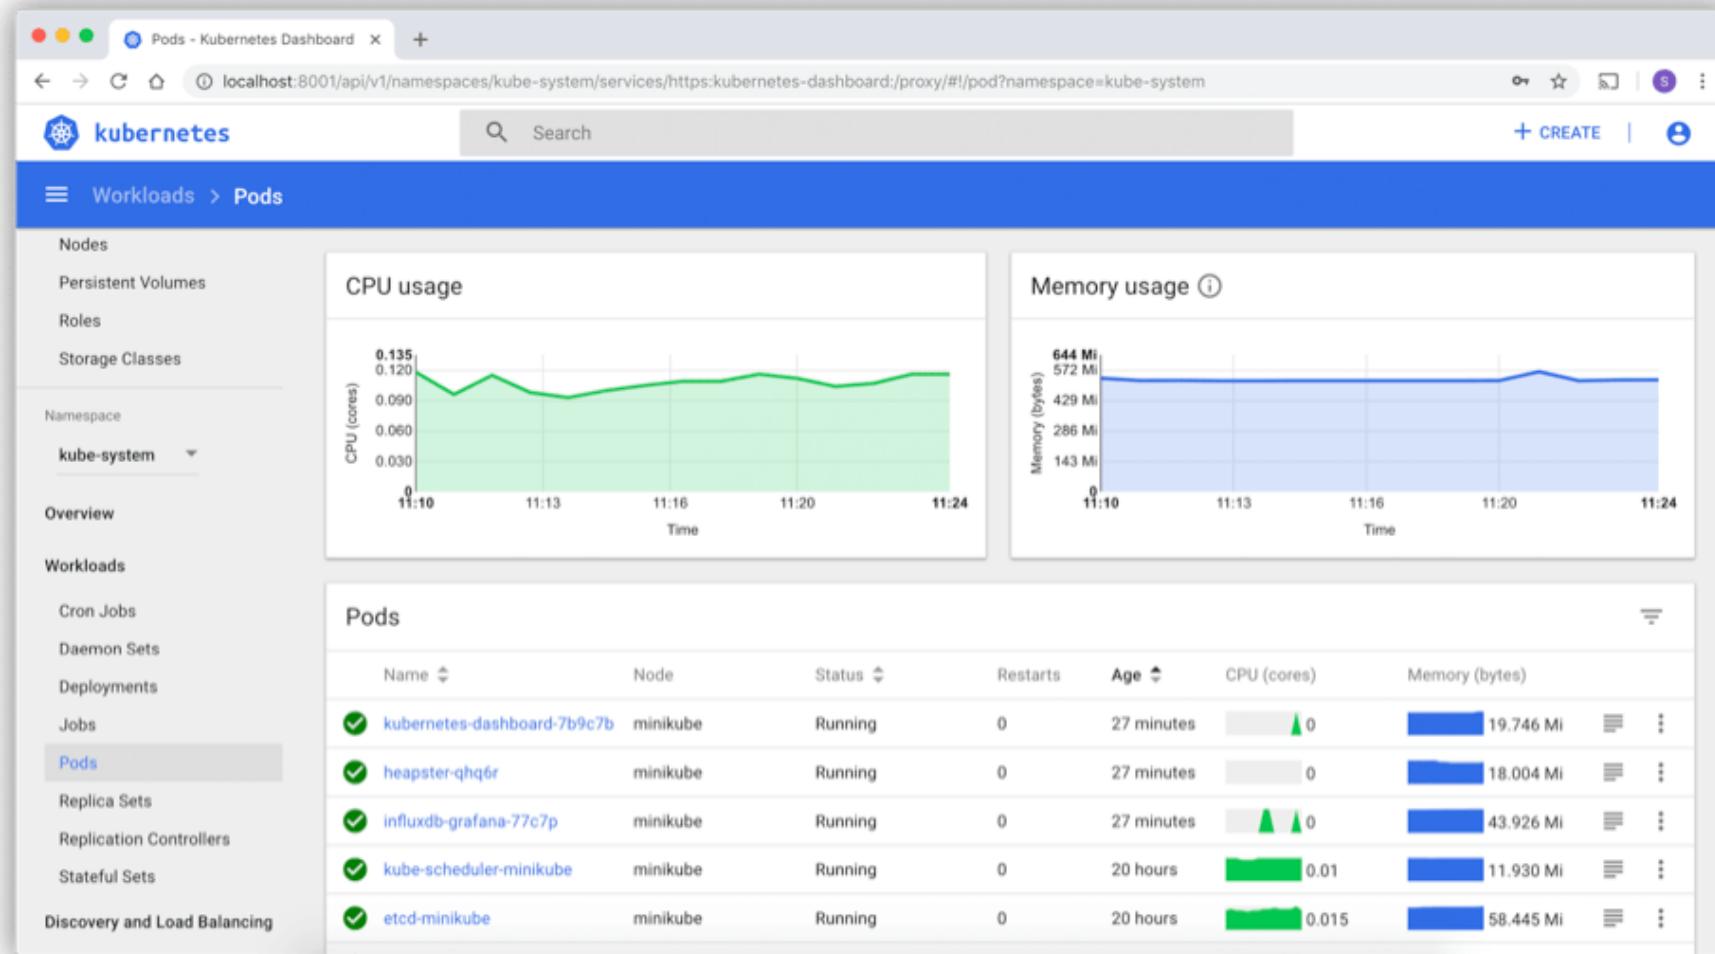

LOAD BALANCING FOR THE K8S CLUSTER

<https://www.a10networks.com/blog/load-balancing-traffic-to-applications-in-kubernetes-cluster/>

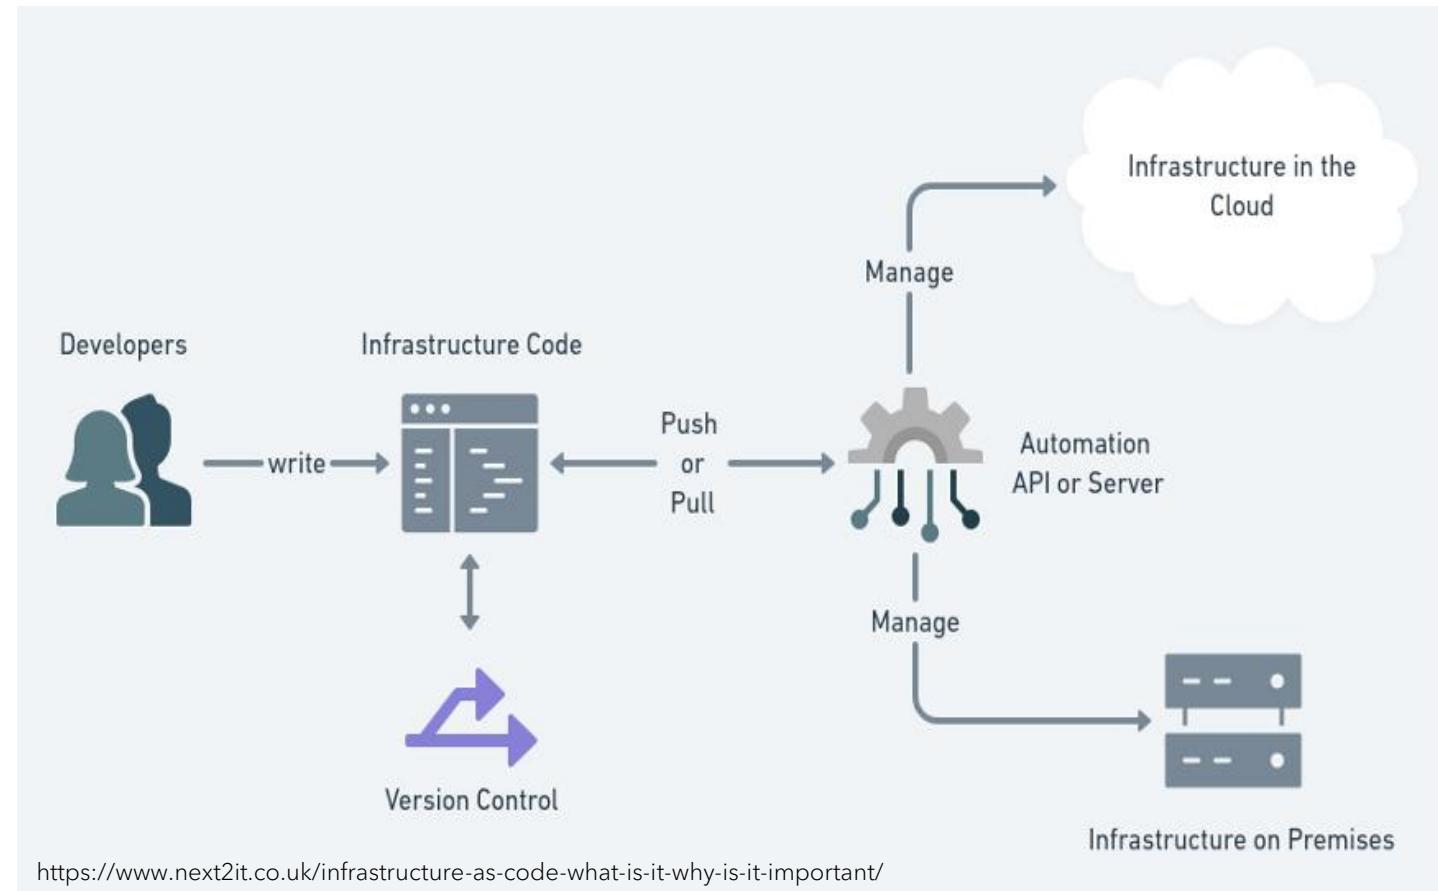

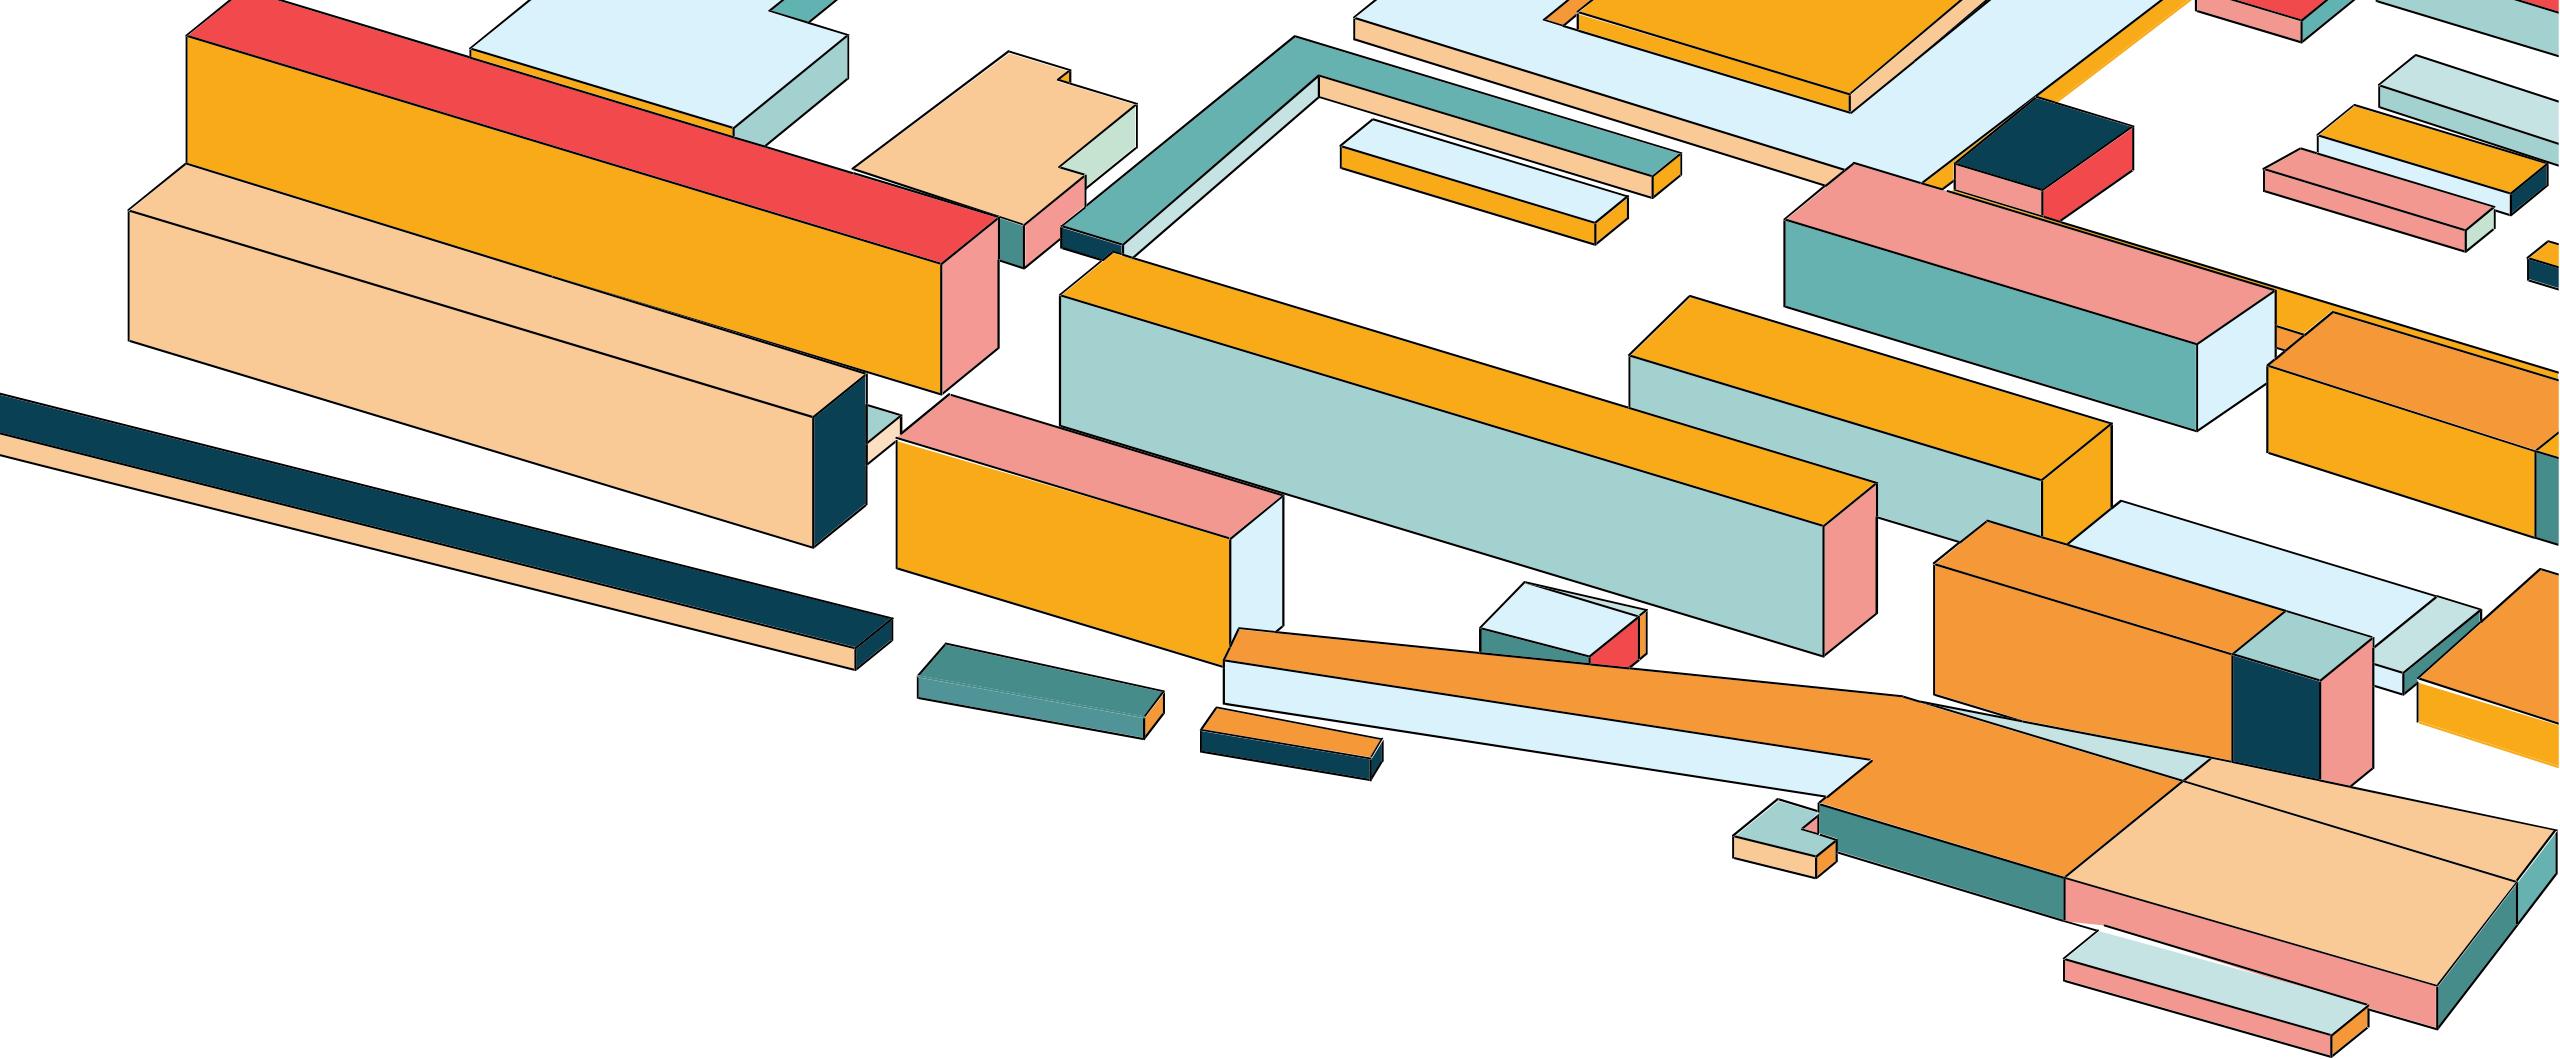

MONITORING THE K8S CLUSTER

INFRASTRUCTURE AS CODE

- Infrastructure as code (IaC) is DevOps practice that involves managing and provisioning infrastructure resources such as servers, networks, storage using code instead of manual processes.
- IaC code is stored in version control systems such as Git, and then executed using automation tools such as Ansible or Terraform.
- Teams can define and maintain their infrastructure as code, just like software applications, and apply best practices such as version control, testing, and CI/CD.

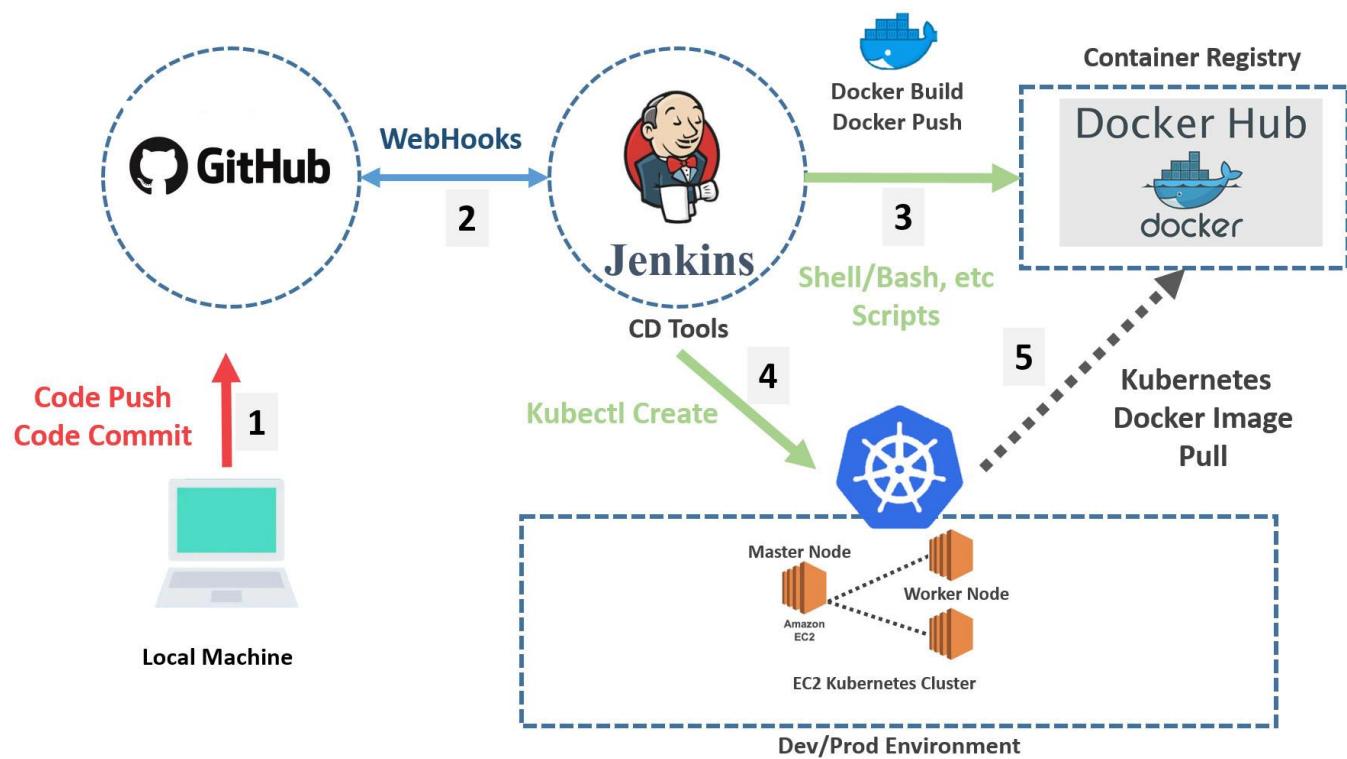

DEPLOYMENT PIPELINES

Jenkins

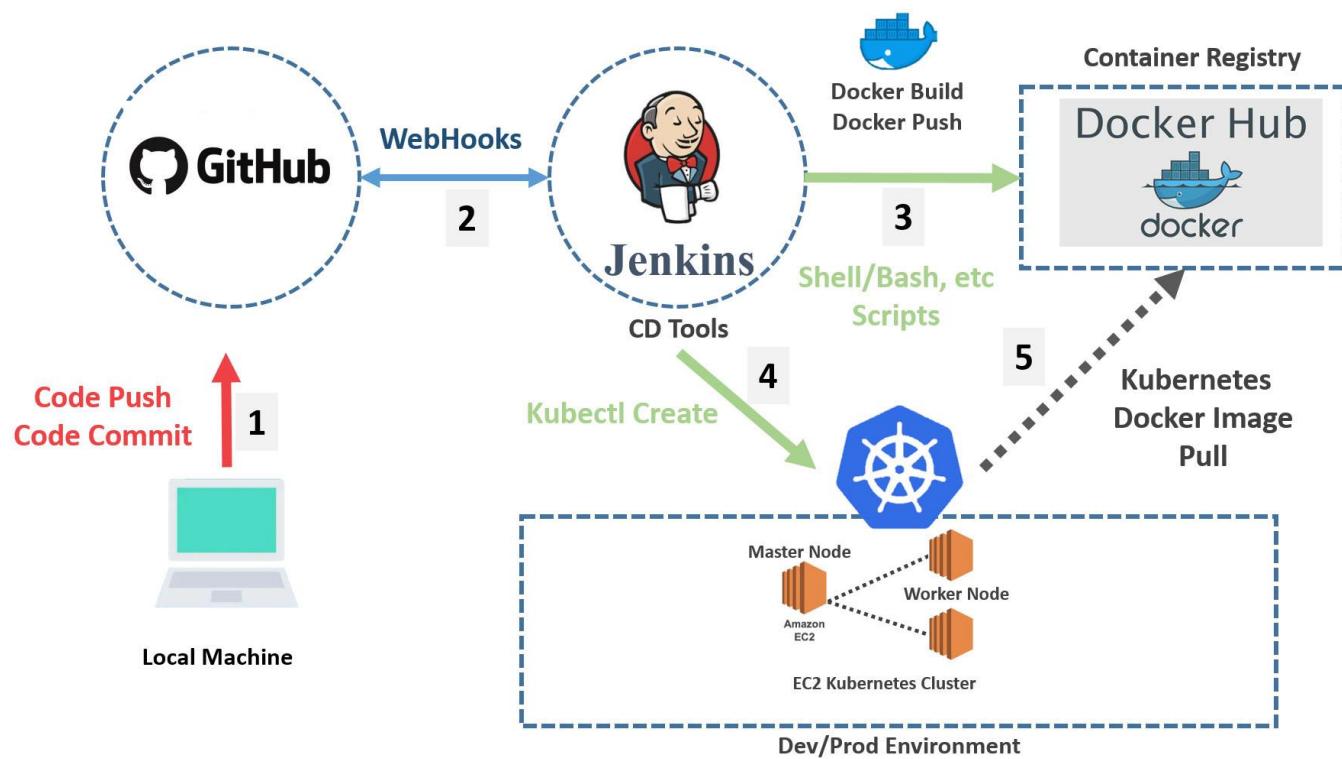

- Jenkins is an open source automation server.
- It helps automate building, testing, and deploying process
- It facilitates continuous integration and continuous delivery.

A TYPICAL JENKINS PIPELINE

Step 0: Configure a [webhook](#) on GitHub, which allows external services like Jenkins to be notified when certain events like push happen.

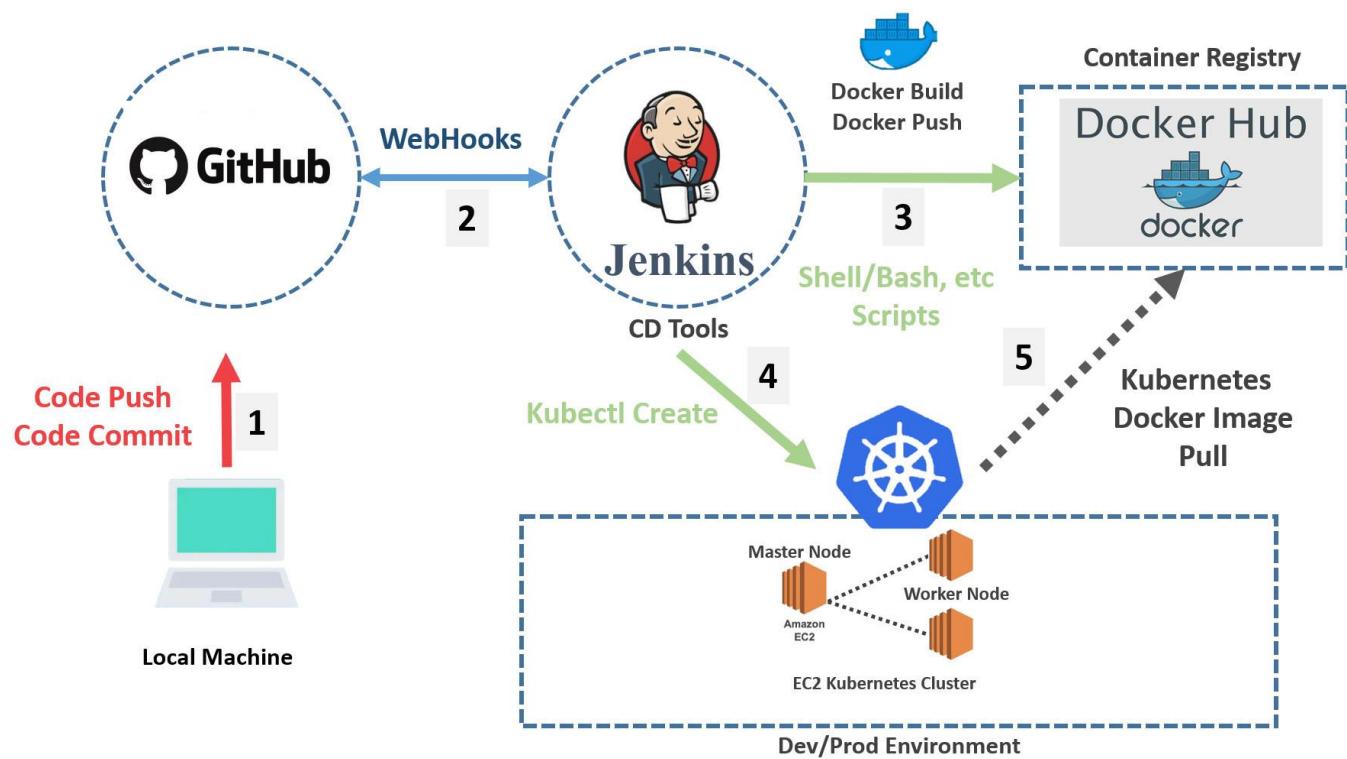

A TYPICAL JENKINS PIPELINE

Step 1: Dev team push local commits to GitHub

Step 2: The push triggers the webhook, and Jenkins will automatically download all the updates from GitHub

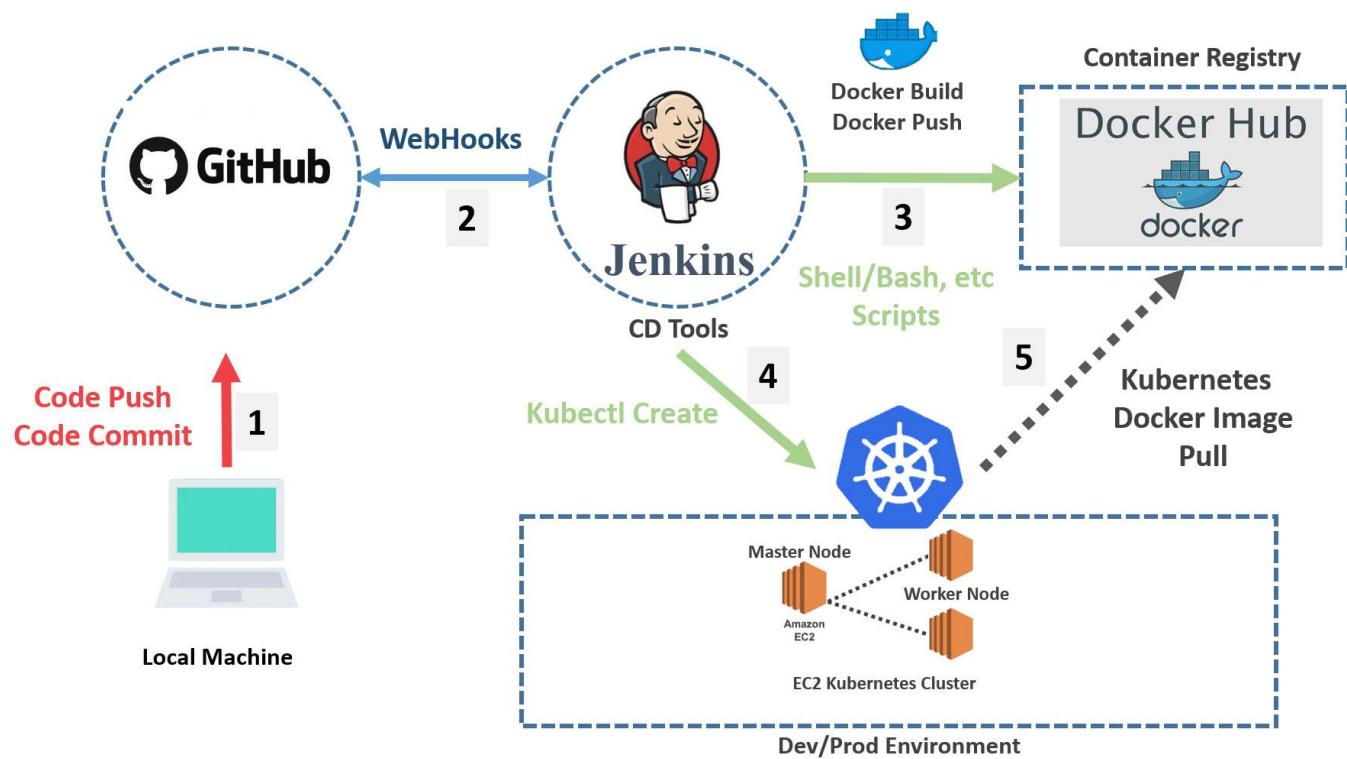

A TYPICAL JENKINS PIPELINE

Step 3: Jenkins could be configured to automatically execute a series of tasks/stages when triggered, for example:

- Build the project with Maven
- Test the project with JUnit
- Build the docker image
- Push the docker image to Docker Hub

A TYPICAL JENKINS PIPELINE

Step 4: Jenkins could also be configured for automatic deployment, e.g., to deploy the software to a K8s cluster

- Step 5: K8s pull docker images from the docker registry

软件开发生生产线 CodeArts

一站式、全流程、安全可信的软件开发生生产线，开箱即用，内置华为多年研发最佳实践，助力效能倍增和数字化转型

为您提供软件开发的一切

华为DevCloud/CodeArts部署流水线

The screenshot shows the DevCloud/CodeArts interface. The top navigation bar includes links for Dashboard, Work, Code, Build & Release, Test, Wiki, Documentation, and Settings. The 'Code' link is highlighted in red. A dropdown menu for 'Code' is open, showing options like 'Code Management', 'Deployment', 'Release', and 'Operation & Maintenance'. Below this, another dropdown for 'Code Check' is shown, with 'Code Check' also highlighted in red. The main content area has tabs for 'Permission Management' and 'Notification'. It features a 'Belonging Project' dropdown, a 'Source Code' section with icons for DevCloud, GitHub, General Git, and Maoyun, and a search bar for repository names. At the bottom, there are two entries with green checkmarks and 'Created' status, followed by a large red-bordered 'Create' button.

1. 创建代码检查(Lint)任务

- 点击“新建任务”，选择需要进行代码检查的代码仓库，点击“创建”
- 待代码检查任务创建成功后，将自动跳转到任务详情页面，然后点击“开始检查”启动任务。任务执行完毕后，就可以查看代码问题列表

华为DevCloud/CodeArts部署流水线

The screenshot shows the DevCloud/CodeArts deployment pipeline configuration interface. On the left, a 'Maven构建' (Maven Build) step is selected, showing its configuration details. The '命令' (Command) field contains the following Maven command:

```
1 # 功能: 打包
2 # 参数说明:
3 #   -Dmaven.test.skip=true: 跳过单元测试
4 #   -U: 每次构建检查依赖更新, 可避免缓存中快照版本依赖不更新问题, 但会牺牲部分性能
5 #   -e -X : 打印调试信息, 定位疑难构建问题时建议使用此参数构建
6 #   -B: 以batch模式运行, 可避免日志打印时出现ArrayIndexOutOfBoundsException异常
7 # 使用场景: 打包项目且不需要执行单元测试时使用
8 mvn package -Dmaven.test.skip=true -U -e -X -B
9
10 #功能: 打包;执行单元测试, 但忽略单元测试用例失败, 每次构建检查依赖更新
11 #使用场景: 需要执行单元测试, 且使用构建提供的单元测试报告服务统计执行情况
12 # 使用条件: 在"单元测试"中选择处理单元测试结果, 并正确填写测试结果文件路径
13 #mvn package -Dmaven.test.failure.ignore=true -U -e -X -B
14
15 #功能: 打包并发布依赖包到私有依赖库
16 #使用场景: 需要将当前项目构建结果发布到私有依赖仓库以供其他maven项目引用时使用
17 #注意事项: 此外上传的目标仓库为DevCloud私有依赖仓库, 注意与软件发布仓库区分
```

On the right, the navigation bar is shown with the 'Build & Release' tab selected. A dropdown menu for 'Pipeline' is open, with 'Build Configuration' highlighted.

2. 创建编译构建(Build)任务

- 选择构建模版：根据实际情况选择相应的模版（例如Maven模版），也可以不使用模版而自定义构建步骤
- 完成配置后，点击确定，自动跳转至构建步骤页面，根据情况编辑各步骤中的配置项，点击“新建”

华为DevCloud/CodeArts部署流水线

The screenshot shows two pages of the DevCloud/CodeArts deployment pipeline management interface.

Top Page (Host Group Management):

- Header: 首页 / DeployMan-UI-L0 / 设置 / 主机组管理
- Toolbar: 适用设置, 项目设置, 云密设置
- Left Sidebar: 基本信息, 成员管理, 通用权限管理, 服务管理, 服务扩展点管理, **主机组管理**, 插件管理
- Main Content: 表格视图显示了多个主机组条目，每条目包含主机组名、描述、操作系统、组内主机数、创建者、创建时间以及操作按钮。
- Bottom: 分页控件显示当前页为10，共178条记录。

Bottom Page (Host Group Creation):

- Header: 基本信息, 主机信息, 设置
- Form Fields:
 - * 主机组名:
 - * 操作系统:
 - 描述:
- Buttons: 保存, 取消

3. 创建部署(Deploy)任务

- 添加部署服务器/授信主机信息
- 新建部署任务，根据实际情况编辑各步骤中的配置项
- 启动任务，执行成功后可以在页面中查看部署日志，也可以登录主机查看部署结果

华为DevCloud/CodeArts部署流水线

4. 配置流水线

- 配置流水线信息，包括基本信息（即流水线名称）、代码源（即选择代码源、仓库与分支）等
- 添加之前创建的代码检查任务、编译构建任务和部署任务。
- 启动任务，待任务执行成功后可单击各任务查看其详情

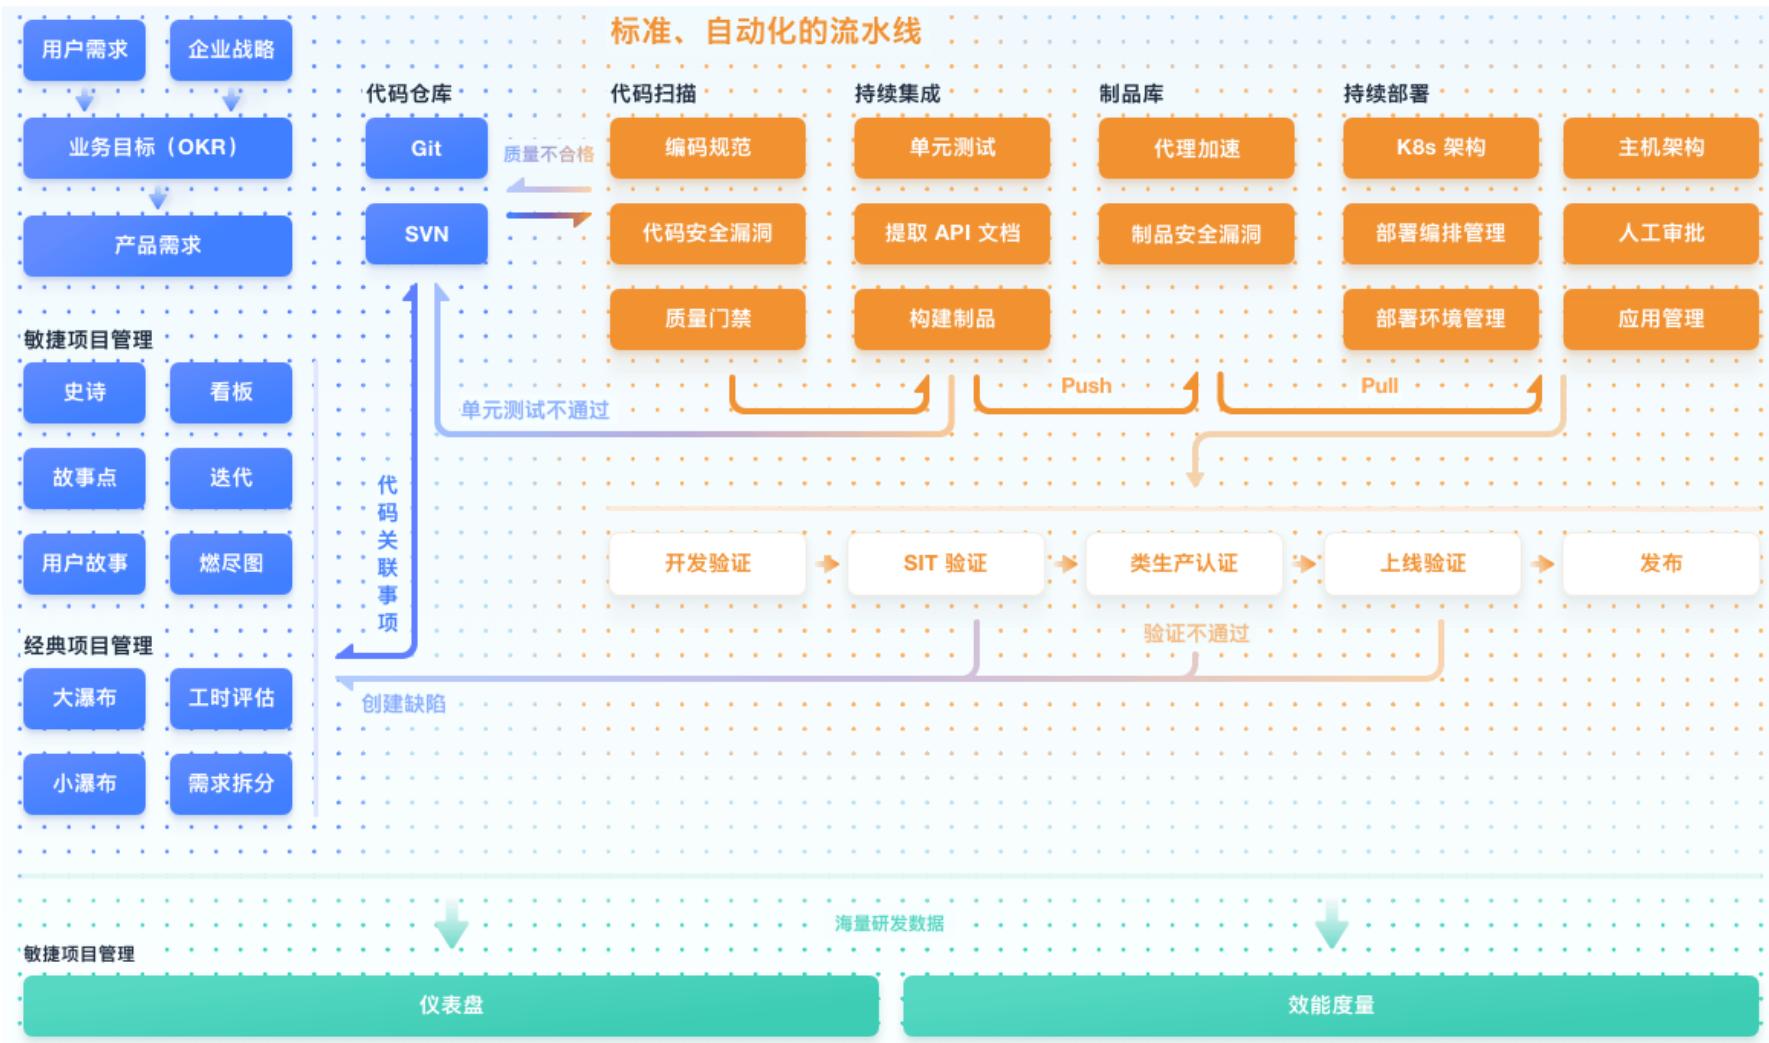

为研发团队打造的 数字化软件工厂

CODING 持续部署

持续、可控、自动化地把软件制品发布到服务集群中，支持蓝绿发布、灰度发布（金丝雀发布）等多种发布策略。

The screenshot shows a screenshot of the Coding.net interface. At the top, there's a navigation bar with 'k8sDemo' (with a dropdown arrow), '浏览' (Browse), '提交' (Commit), '分支' (Branch), '合并请求' (Merge Request), '版本' (Version), '对比' (Compare), '设置' (Settings), a status indicator '•已开源' (Open Source), a '创建代码仓库' (Create Repository) button, and a dropdown menu.

The main area shows a file browser on the left with a tree view of the 'k8sDemo' repository. The 'k8s' folder contains 'deployment....yaml' and 'service.yaml'. Other files include 'gradle/wrapper', 'lib', 'src', '.gitignore', 'Dockerfile', 'build.gradle', 'gradlew', 'gradlew.bat', and 'settings.gradle'. The current file being edited is 'deployment....yaml'.

The code editor shows the 'deployment....yaml' file content:

```
apiVersion: apps/v1
kind: Deployment
metadata:
  labels:
    app: k8sdemo
  name: k8sdemo-deployment
  namespace: cd-demo
spec:
  replicas: 1
  selector:
    matchLabels:
      app: k8sdemo
  template:
    metadata:
      labels:
        app: k8sdemo
    spec:
      imagePullSecrets:
        - name: coding-registry-cred-252585
      containers:
        - image: 'StrayBirds-docker.pkg.coding.net/flask-demo/cd-demo/hello-world'
          name: k8sdemo
          ports:
            - containerPort: 8080
```

At the bottom right of the code editor, there are '提交' (Commit) and '取消' (Cancel) buttons. Above the code editor, there are buttons for '克隆' (Clone) and a dropdown menu.

<https://coding.net/help/docs/cd/best-practice/circle.html>

CODING 持续部署

持续、可控、自动化地把软件制品发布到服务集群中，支持蓝绿发布、灰度发布（金丝雀发布）等多种发布策略。

The screenshot shows a web-based development environment for managing Kubernetes configurations. On the left, a sidebar displays the project structure of 'k8sDemo' with files like 'gradle/wrapper', 'k8s', 'deployment...', 'service.yaml', 'lib', 'src', '.gitignore', 'Dockerfile', 'build.gradle', 'gradlew', 'gradlew.bat', and 'settings.gradle'. The 'service.yaml' file is selected and shown in the main editor area. The code content is as follows:

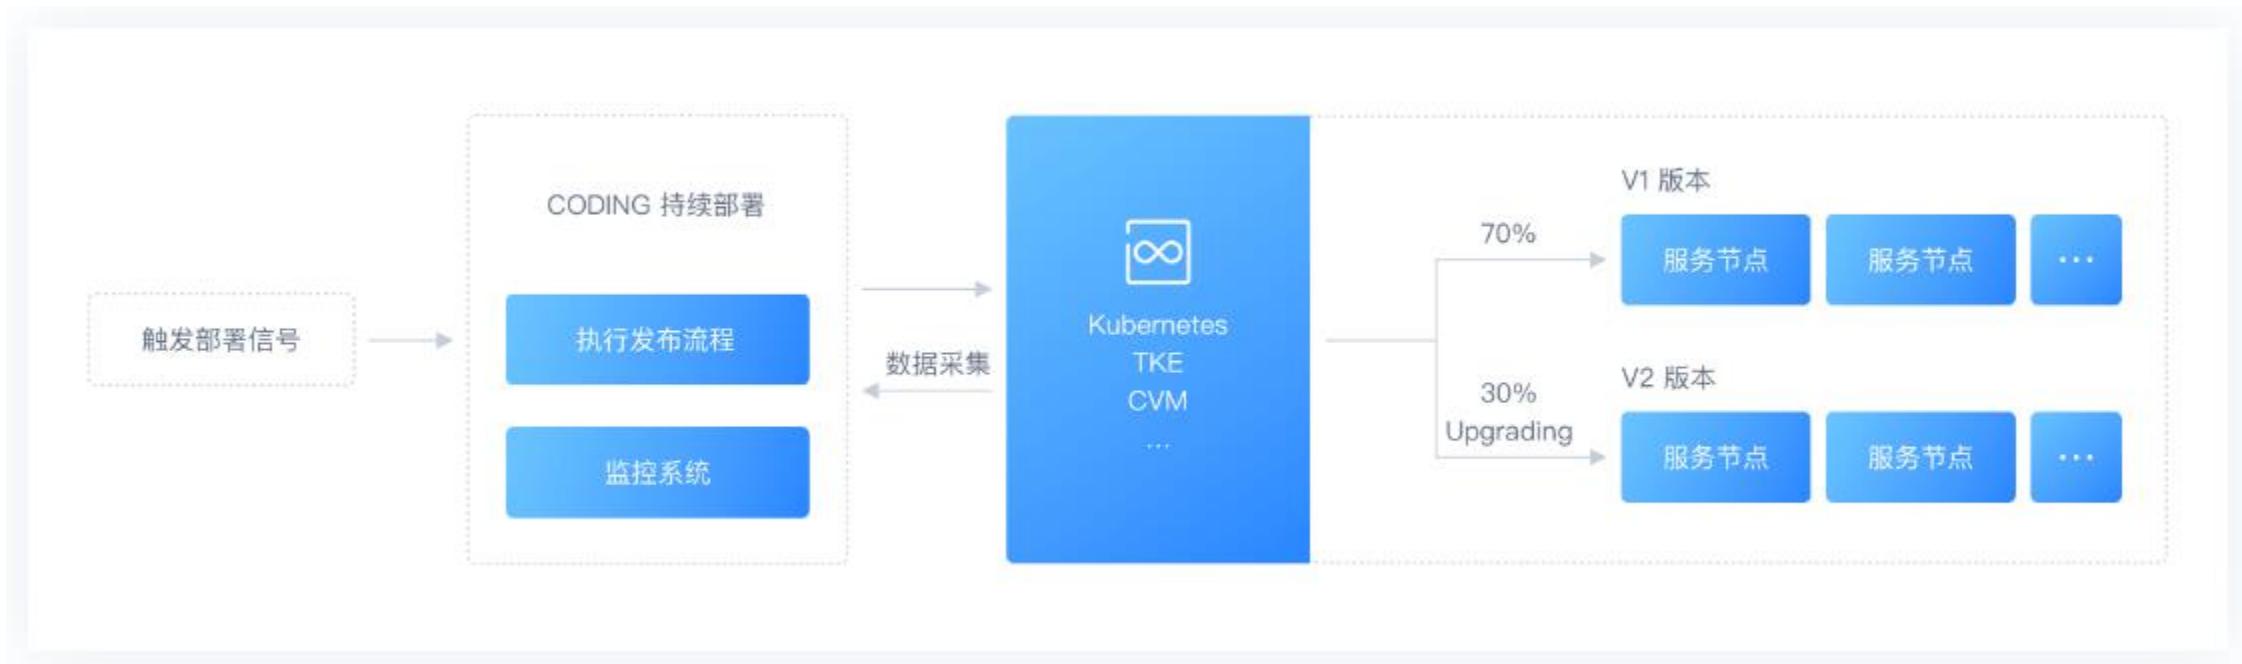

```
apiVersion: v1
kind: Service
metadata:
  name: k8sdemo
  namespace: cd-demo
spec:
  selector:
    app: k8sdemo
  ports:
    - port: 8080
      targetPort: 8080
  type: LoadBalancer
```
